Foreword

The Indian Institute of Astronomical & Sanskrit Research has done a very useful piece of work by publishing the Brāhma Sphuṭa Siddhānta. This is an original work on Astronomy written about twelve hundred years ago. Mainly devoting himself to Astronomy as was natural, the author, Brahma Gupta, has also given considerable space to such branches of Mathematics as in his opinion are particularly applicable to Astronomy. Brahma Gupta is not a mere theoriser. His work bears ample evidence of close observation of astronomical phenomena, though he did not have at his disposal any large and well equipped Vedhālaya or Observatory. He has had to find fault with some of his predecessors. The main reason for his criticism was as stated by him :

ब्रह्मोक्तं ग्रहगणितं महता कालेन यत् श्लथीभूतम् ।

अभिधीयते स्फुटं तज्जिज्ञसुतब्रह्मगुप्तेन ॥

The creator Brāhma himself had given certain calculations in his book namely Brahma Siddhānta. But in the course of many years these calculations have been found to have become inaccurate. Of course, in referring to calculations, the author is referring to the bases of these calculations, the main data of astronomy. The excellent and fairly exhaustive introduction by Dr. Satya Parkash is of very great help in understanding the book because it brings out clearly the various points on which Brahma Gupta has laid stress, particularly those on which he differs from other great astronomers.

A great controversy still rages between two schools of Indian astronomers which for want of better names may be called the schools of Arya Bhata and Brahma Gupta. Some years ago the Indian Institute of Astronomical & Sanskrit Research published the Vateshwar Siddhānta which is supposed to be associated with the Arya Bhata School. It is, therefore, in the fitness of things that it should now publish the present standard volume of the other school.

To my mind the Publication of such books is of great value from two points of view. It helps to remove the ignorance of average educated Indian of today about the achievements of his ancestors. In the field of two important branches of science, Mathematics and Astronomy, it is really surprising how those ancient astronomers could reach such heights of accuracy with the help of instruments which seem to be laughably crude compared to those that modern astronomers have at their disposal. At the same time a study of such literature is a very salutary corrective

to the vanity of those who feel that in astronomy as in certain other subjects the last word was said by those writers who have written in Sanskrit. We learn how far behind we are in certain very important directions in the field of knowledge.

It is interesting by the way to find that the author of this great work was a Vaishya. This shows how diffused knowledge even of the most abstract subjects was in those days and how Scholarship was honoured irrespective of caste. Not one the critics of Brahma Gupta has taunted him on the ground of his not being a Brahmana.

Sampurnanand
Governor-Rajasthan

Raj Bhavan,
Jaipur,

Dated May 4, 1966.

Observations

of

Dr. K. M. Munshi

President of the Reception Committee

The Author Shri Ram Swaroop Sharma has given to the world of scholars an excellent and valuable treatise on the famous Astronomer Brahma-Gupta, son of Jisṣugupta, born in 589 A. D. in Bhillamala or Srimala now in Southern Marwar close to the northern frontier of modern Gujarat. The work is divided into 13 chapters and at the end of each, the learned author has given reference to other works and treatises for further study as also in support of his various conclusions. He has described Astronomy in Ancient India in the light of the knowledge of the subject available in different countries in his time.

After giving personal details of Brahma-gupta, the author starts on a critical study of the works of that Astronomer-particularly his *Brahma-sphuta-siddhānta* and *Khandana-Khādyā*. The author has also discussed the Indian Luni-solar Astronomy, the Greek and Hindu methods in spherical Astronomy and the Epicyclic theory of ancient Indians. Discussing in detail the contribution of Brahma Gupta in Arithmetic, Algebra, in Astronomy and the Astronomical instruments that he used, the author has brought out the various highlights of his work and achievements in comparison with those of his predecessors, successors and contemporaries in other countries.

The author deserves to be congratulated for this scholarly contribution on the subject of Ancient Indian mathematics and Astronomy.

—K.M. Munshi

Bhartiya Vidya Bhawan
Bombay

Publisher's Note

It is with pride and pleasure that the Indian Institute of Astronomical & Sanskrit Research brings out its second monumental work 'Brāhma Sphuṭa Siddhānta'. The Institute, set up on the 23rd November, 1957, with the object of promoting research into ancient Indian manuscripts on Astronomy and allied Sciences, started its programme of publication with the preparation of a critical edition of Vateshwara Siddhānta running into more than 700 pages. It was far back in early forties that the idea of reviving the treasures of knowledge hidden in ancient manuscripts came to my mind. In 1945 I could succeed in editing and publishing 'Trailokya Prakāśa' of Acharya Hemā Prabha Sūri.

Ālbruni's Travel Accounts of India contain a reference to Vateshwara Siddhānta and this fact was responsible for prompting me to arrange publication of Vateshwar Siddhanta. It was rather difficult to search out this manuscript and the clue given by Mahamahopadhyaya Sudhākar Dwivedi (a great Mathematician and Astronomer of 19th century) that the manuscript was available in Gwalior did not lead me to any results. I kept my search on and found a copy of this text in the collection of manuscripts inherited by a Brahman widow of Gujranwala District in west Pakistan. The same style of copy was later seen by me in the Panjab University Library at Lahore.

Vateshwarāchārya, the great writer of Vateshwara Siddhānta, has criticised Brāhma Sphuṭa Siddhānta of Brahma Gupta, in his work. This naturally aroused my curiosity to procure and publish Brāhma Sphuṭa Siddhānta so as to provide right perspective to the students of ancient Indian Scientific literature. Moreover, in one of my discussions with the late Dr. K. S. Krishnan, Director, National Physical Laboratories, New Delhi, he referred to Dr. Colebrook (a German Writer) as having translated into English two chapters of 'Brāhma Sphuṭa Siddhānta', namely, Vyakta (Arithmetic) and Ayakta (Algebra). The late Dr. Krishnan showed keen interest in this manuscript and encouraged me in taking up preparation of a critical edition of this text. The Institute is grateful to the Govt. of India (Department of Cultural Affairs) for meeting part of the expenditure on this publication and thereby enabling us to complete our task.

I shall be failing in my duty if I do not mention the great and invaluable contribution made for the success of the Institute by its founder President the late Shri Brijlal Nehru. It was under his able guidance that the Institute started functioning and its various programmes were finalised. His passing away has been a big and irreparable loss to us. The Institute will keep his memories always alive by following his ideals and by executing with zeal the programmes inspired by him.

I must take this opportunity to express my heartfelt gratitude to Shri B. B. Varma, Member Parliament, who has never shirked in shouldering the responsibilities of managing the affairs of the Institute first as a member of its Executive Council and now as its President. I am also thankful to Dewan Hari Krishan Das, Chairman of the Executive Council and Shri F.C. Bedi Treasurer of the Institute for their ungrudging support to the cause of the Institute.

My thanks are also due to Dr. Sampurnanand, Governor Rajasthan, who has blessed the Institute by inaugurating it and has now been kind to write a foreword for the present book. I am also indebted to Dr. Satya Prakash, Head of the Deptt. of Chemistry, Allahabad University for his having spared time to write an introduction in English for this publication. He has always been cheerfully allowing us to draw on his rich experience and wealth of knowledge. I am also grateful to Pt. Mukund Mishra, Pt. Vishwa Nath Jha, Shri Daya Shankar Dixit and Pt. Om Datt Sharma, the learned scholars who helped me in preparing this work.

The book has been published in four volumes. Volume I includes introduction in English by Dr. Satya Prakash followed by the text as given in the copy of the manuscript obtained from the Bhandarkar Research Institute, Poona, with footnotes to collate the various versions found in the copies of the manuscripts procured from the Royal Asiatic Society, Bombay, the Oriental Research Institute, Baroda and the Vishweshwaranand Vedic Research Institute, Hoshiarpur. The volume also contains a Sanskrit Bhumika from the Chief Editor and an Index of Shlokas. Volume II comprises of the first nine chapters of Brāhma Sphuṭa Siddhānta containing only those readings which we have considered as correct. It also includes Vāsana commentary of Pṛthūdaka Swāmi and Vigyān Bhashya in Sanskrit with Hindi translation. Volume III includes chapters 10 to 16. This volume also contains Nutan Tilak commentary of Sudhakar Dwivedi and Vigyan Bhashya in Sanskrit with Hindi translation. Volume IV comprises of chapters 17 to 24 and also an Index of Shlokas contained in Volumes II, III and IV. It also includes an appendix on Dhayāna Grhaṇādeshadhyāya. Another appendix in this volume contains Vāsana commentary on Golādhyāya.

The Institute has planned to add to its list of publications, shortly, Samrāt Siddhānta (3000 pages and already in press), Brhad Yavan Jātaka (2000 pages) and Panch Siddhāntikā (1600 pages).

The Indian Institute of Astronomical & Sanskrit Research considers it a proud privilege to dedicate Brāhma Sphuṭa Siddhānta to Shri S. K. Patil, Union Minister for Railways. I am highly grateful to him for his having consented to this dedication. I am also grateful to Shri K. M. Munshi and Shri Wadilal Chaturbhuj Gandhi for their kindly agreeing to my request to be President and Chairman respectively of the Reception Committee. My heart felt thanks are also due to Shri Kanti Lal H. Shah, Hony. Secy. of the Organising Committee and to all the members of the organising and the Reception Committees for their help and cooperation in my work. I also owe a debt of grati-

tude to the Patrons of the Institute : His Majesty the King of Nepal, Abhinaya Samrat, Shri Prithvi Raj Kapoor, Shri Dhairyasingh, R. Morarji, Chairman Dharamsi Morarji & Co., Bombay, Shri Pranlal Bhogilal, Patel Bombay for their invaluable help. I am also grateful to the life members of the Institute : H.H. Maharaja Manabendra Shah of Tehri Garhwal, Yuvraj P.C. Dev, Shri B.N. Bhaskar, Shri R.K. Batra, Shri Sada Jivatlal Chandulal, Shri Shiv Kumar Bhuvalka, Shri Jainna Das H. Moorjani, Shri Shantilal K. Somaiya, Shri Kisonlal M. Diwanji, Solicitor, Shri N. K. Jalan, Shri D. R. Nayar, Shri Vadilal C. Gandhi, Shri Devi Prasad Khandelval, Shri Ram Prasad Khandelval, Shri B. K. Jalan, Shri Amir Chand T. Gupta, Shri Laxman Vaman Apte, Smt. Padma Koregaonkar, Shri Yodh Raj Bhalla for their support to the Institute.

I must make a special mention here of shri A.N. Jha, Chief Commissioner, Delhi, who has greatly encouraged me in my task of publishing old manuscripts. His help in solving the various problems faced by me, has been invaluable. I am highly grateful to him for his support in my cause. I am also grateful to H. H. Maharaja Manabendra Shah of Tehri Garhwal, Seth Sadajivat Lal, Smt. Padma Koregaonkar, Lala Yodh Raj Bhalla, Shri F.A. Fazalbhay, Shri Morar J. Vaidya, Shri N. J. Aggarwal, Shri P. S. Naulakha, Shri R. L. Maheshwari, Shri D. N. Bhattacharjee, Shri P. A. Narainwala, Shri P. M. Aggrawal, Shri Shiv Kumar Bhuvalka, Shri Navin Bhai Khandwala and Smt. Nirmala Gonde, Lala Jagan Nath Ji, Shri L.S. Aggarwal, Shri B.N. Saxena, Shri R.B. Shah, Shri L.O. Joshi, Shri T.S. Krishnamurti, Shri R. S. Chitkara, Dr. Ram Karan Sharma, Shri V.P. Agnihotri, Shri K.L. Handa and Shri K.G. Somayya for their help and advice at various occasions.

Astronomy in Ancient Nations

Brahmagupta's great works like the *Khandakhadyaka* and the *Brāhma-sphuṭa-siddhānta* took astronomy to Arabs through whom it spread to many countries of Europe. Al Beruni records this testimony in his great book on India. It is doubtful that astronomy had its birth in Greece and China. From remote ages China, India, Greece, Arabia and Egypt developed the entire system in close cooperation. This knowledge must have spread from their common cradle home where man for the first time developed his culture and civilisation. In this chapter we propose to give a review of astronomy as developed in many of these ancient lands, especially Arabia, people of which land came in close contacts with India much before any recorded time.

Dawn of Astronomy

The earliest man must have been the primitive astronomer. The striking spectacles presented to him by the varied appearances of a sky covered with thousands of twinkling and non-twinkling objects of different degrees of brightness, apparently revolving round the Earth, and the daily changing phases of the Moon must have raised strange feelings of the most primitive man also. Then he must have in course of time observed the bright morning and evening stars, and at a considerably late stage the comets and shooting stars and then on occasions eclipses of the Sun and the Moon. These phenomena not only raised feelings of admiration, but in different sections of human society often feelings of superstitious alarm. By and by stars became guides for the traveller by land and sea. In the midst of these observations, one discovered various cycles: cycle of day and night, cycle of seasons and cycle of other details. Then there was a striking observation of the tides in a sea changing with the phases of the Moon.

Earliest Discoveries

We shall briefly sketch out the order of astronomical discoveries. The first phenomena to be noted must have been the regularly recurring dawn (for this one may refer to the *Uṣā Sukta* of the *R̥gveda*), the sunrise and sunset (which led to *prātaḥ* and *sāyam*, i.e. morning and evening prayers of the Vedic times), daylight, twilight and night concerning which we have numerous Vedic hymns. Next it led to the measurement of a day (which was of a short duration in winters and of a long duration in summers). The Vedic Aryans also discovered the variations in the duration of the day along different latitudes, and the time of sunrise in places of different longitudes. In fact the idea of longitudes and latitudes came sufficiently afterwards. Man discovered month as related to the variation of light with the Moon's phases. In temperate regions, where probably the first astronomical observations were systematically made, the changing length of the day or the direction of the Sun at rising or setting or the lengths of shadows cast at midday, would show that the Sun's daily path in the sky altered throughout the year, a time interval which was already marked by the changing vegetation. According to Sir W.C. Dampier, "attempts were made to determine the number of months in the cycle of the seasons in Babylonia about 4000 B. C. and in the China soon after. About 2000 B. C. the Babylonian year settled down to one of 360 days or twelve months, the necessary adjustments being made from time to time by the interposition of extra-months." In India, this concept is of even much earlier origin. The old inspired sages like *Dirghatamas* discovered for the observing man the Vedic Era and intercalation. I have described this discovery in a special chapter on the subject in my book the *Founders of Sciences in Ancient India* and a reference may be made to the *Āśya Vāmasya Suktam* of the *R̥gveda*. It is impossible to assign an age to these old traditions. Round the *Yajña*, developed the science of astronomy, mathematics, anatomy and medicine in this ancient land of ours, which in fact was the common heritage of a large number of people of the modern world.

One might also say that a considerable period might have well elapsed before it was noticed that at a particular season of

the year, the same stars are seen at corresponding hours of the night. Of course this circumstance was less conspicuous than the regular variation of the Sun's altitude in the sky as the year progresses. It is the surmise that the striking naked-eye cluster, the Pleiades, must have been one of the earliest noted star-groups, and it became the first star-group for providing the first fairly close determination of the length of the year as approximately 365 days. The rising of this cluster in the evening was a mark of the coming winter to primitive man; and the husbandman judged the time of reaping by its rising, and of ploughing by its setting in very ancient times; Sirius, Arcturus, the Hyades and Orion were similarly equally useful to him. The passages in the *Taittirīya Samhitā* and in the *Śatapatha Brāhmaṇa* clearly indicate the confusion once created by following the concept of lunar months without further adjustments:

"Now the seasons were desirous to have a share in the sacrifice among the gods and said, 'Let us share in the sacrifice. Do not exclude us from the sacrifice! Let us have a share in the sacrifice!' The gods, however, did not approve of this. The gods, not approving, the seasons went to the Asuras, the malignant, spiteful enemies of the gods. Those (Asuras) then throve in such a manner that they (the gods) heard of it, for even while the foremost (of the Asuras) were still ploughing and sowing, those behind them were already engaged in reaping and threshing: indeed even without tilling, the plants ripened forthwith for them. (ŚBr. I.6.1.1-3)

The Zodiac

It is difficult to say how much time it must have taken, but in fact, it was eventually noted that the Sun and Moon travel over very similar paths among the stars during their circuit of the sky. This led to the formation of the Zodiac and its constellations, the centre of this zone, a belt about 16° broad, being the annual path of the Sun or Ecliptic. The division into twelve parts, each corresponding to a month of the Sun's movement, was made; and their connection with the solar course during the year was found by observations of heliacal risings or settings. These were the times of the year when certain bright stars would first be seen to rise before the Sun, or when

they were last seen to set after sunset. In the case of *Sirius*, the brightest fixed star, these would happen when the Sun was about ten degrees below the horizon. For the less bright stars the angle would be a larger one.

It must have been almost simultaneously observed that the Moon in going like the Sun round the heavens always in the same direction from west to east (i. e., opposite to the diurnal motion which she shares with the other bodies), kept in general to the same track in the sky. After a time, however, it must have been noted by careful observers that this path was not constant, but deviated from the centre line of the Zodiac, getting away from that line up to a maximum deviation on either side but slowly returning to it. In the course of a number of years, it must have become evident that the Moon's path among the stars does not lie always in the same line on the celestial sphere, but in a zone or band about twenty moon breadths (10°) wide, occupying the middle of the Zodiacal zone itself.

Among the bright stars Mercury, Venus, Mars, Jupiter and Saturn (the first two of which are never seen very far from the Sun in the sky) soon must have been noted to be moving in the Zodiac with varying periods. The English name *planet* is derived from Greek *planetes*, meaning a wanderer, since the planets change their positions among the Zodiacal stars.

There is a word *Str* which in the *Rgveda* always occurs in the instrumental plural, *Strbhiḥ*. The English word star is derived from this word. Parāśara and Ṛṭsamada, I have shown elsewhere, were the first amongst the great observers, inspired by the *Rgvedic* hymns, and Vāmadeva identified *Bṛhaspati* or the Jupiter planet and Vena *Bhārgava* discovered the planet Venus which still bears the name of its discoverer.

Constellations

Long before the Zodiacal belt was divided into "signs" (700 B. C.), a number of asterisms, or the configuration of stars in the sky had been arranged, the brighter stars of these configurations, thus identified, proved very useful in indicating the seasons of the year by the times of their rising or setting, and also in locating the positions on the celestial vault of such moving objects as planets, comets and shooting stars and in helping the traveller by land or sea to determine direction.

These named constellations date back to very early period. In India, Gārgya is the name of an astronomer who is associated with a hymn of the *Atharvaveda* which for the first time enumerates constellations. In many of these constellations, the stars form a well marked group, clearly separated from other groups, and the names given to these formations are supposed to have been suggested by a resemblance to the shapes of certain familiar objects. Of course, the resemblance is usually very slight, and depended merely on a fancy.

It is remarkable that different countries developed almost similar notions regarding these constellations. The late Dr. A. C. D. Crommelin considered that there is a reason to believe that the stars may have been grouped to some extent by the Egyptians as early as 4000 B. C., and he remarked on their use of the then Pole Star for orienting the Great pyramid. Again, Chinese are said to have mapped out the sky into many divisions of stars by 2500 B. C., if one can rely on their records.

The idea of constellations takes us to a date much earlier than 2500 B. C. even. In total forty-eight have come down from extremely ancient times, but these do not cover the entire extent of the sky. The part not occupied by any of them evidently did not rise above the horizon where the early astronomers to whom we owe their naming lived; and the stars concerned were therefore not included in their constellation schemes. The centre of this part (near the bright star Achernar) must have been near the South Pole of the heavens of the time, and its angular radius from the Pole gives us roughly the latitude of their homes. The date appears to have been about 2800 B. C., when, owing to the precession of the equinoxes, the South celestial pole was in the position indicated. The latitude seems to have been about 38° North. These are the findings of E. W. Maunder (*Astronomy without a Telescope*, p.5, 1902); but from the same considerations Dr. Crommelin assigns a latitude of 36° and a date 2460 B.C. and Proctor 2200 B. C. Maunder also suggested that the presence of the Lion and Bear among the stellar configurations and the absence of Elephant, Tiger, Camel and Crocodile seem to exclude India towards the East and the countries towards the West, the latitude and the longitude indicated being those of Asia Minor or Armenia. The suggestion that the blank area in

the sky referred to gave an approximate date for the formation of the constellations appears to have been first put forward in 1807 by Carl Schwartz, for some time Swedish Consul at Baku.¹

Indo-Greek Contacts

It is highly improbable that before Alexander, there had been absolutely no contacts between India and the distant nations. Even in pre-Alexandrian era, there had been such migration is clearly evinced by the philological and mythological studies. But we do not possess historic record of it.

The conquests of Alexander the Great made the Greeks acquainted with the Eastern world, which had up to that time been visited probably by very few Europeans, and it likewise spread Greek culture to all the countries which the victorious Macedonian had been able to reach. The Indian province of his Empire became independent soon after Alexander's death, and though the spread of Buddhism in the third century B.C. checked the progress of Hellenism in Northern India, the rise of the Greek kingdom of Bactria and its gradual extension south and east continued for a long time to keep alive the connection between India and the West. Not only (as has been asserted) the Greek and Indian drama and architecture have been strongly influenced by Hellenistic and Indian contacts, it is beyond a doubt that the entire astronomy of the two great nations is the offspring of these mutual contacts.

In earliest times astronomy had only been cultivated in India and in no other country. Some idea had been acquired during those days of the periods of the Sun and Moon and the planet Venus and Brhaspati (Jupiter), which were used for chronological purposes, the lunar motions being specially connected with the proper times for sacrificial acts. The Vedic era was discovered during this period by Viśvāmītra, and Gargya enumerated the Nakṣatras. Lagadha composed his *Vedāṅga Jyotiṣa*, which is the first book on astronomy written in human literature. India developed her geometry in connection with the construction of sacrificial altars, and its account is found in the *Sulba Sūtras* of Baudhāyana, Āśvalāyana and Kātyāyana. Āryabhaṭa laid the foundations of algebra. One might still say that there is no sign of

1. See, Peter Doig: *A concise History of Astronomy*, London, 1950.

accurate knowledge of the planetary motions earlier than about the century of the Christian era. From thenceforth astronomy, hitherto confined to rituals, appears as a science, treated in the course of the next thousand years in a series of text-books, the *Siddhantas*,¹ the contents of which, though supposed to be derived from divine sources are strongly influenced by Greek authors. Prior to the Greek influence, we had ceremonies like *dvādaśāha* (lasting for twelve days), *ṣaḍāha* (lasting for six days), *tryāha* (lasting for three days) besides *darśa-pūrṇamāsa* ceremonies connected with the New Moon and Full Moon. But the week of seven days (*Saptāha*) was unknown in India. This concept of week and the dedication of each day to the deity of one of the seven planets, now appears for the first time. It is difficult to say whether names of the planets were borrowed by Greeks from India or vice versa, but they became common, e.g., *Aśvajit* or *Asphudit* (Aphrodite). *Dyugatiḥ* or *dyaus* or *Jīva* (Zeus), *Heli* (Helios), &c., while the zodiacal signs have superseded the earlier but totally different twelve star-groups connected with the Sun's motion, and proclaim their origin by their names:

Kriya, Tāvuri, Jituma, Karkin, Leya, Pāthēna, Juka, Kaur-pya, Taukshika, Ākokerā, Hridroga, Ittha,

corresponding to *Κριός, Τοῦρος, Δίδυμος, Καρκίνος, Λέων, Παρθένος, Ζυγόν, Σκορπίος, Τοξότης, Αιγόκερως, Ἰχθύς*.

A great many other Greek terms connected with geometry, astronomy and astrology have also been transferred from Sanskrit works to Greek and vice versa. This conclusively shows the mutual influence on astronomy. Indian authors never failed to acknowledge the ideas they borrowed from Greeks, e.g. Varāhamihira quotes the Yavanas or peoples of the west as authorities for some of the scientific statements he makes. The name of the *Romaka Siddhānta* (which is at least as old as A.D. 400) also points in an unmistakable manner to its origin in one of the provinces of the Roman Empire.

1. The *Romaka* or *Paulīśa Siddhānta* (before 400 A. D.), See Varāhamihira's the *Pañcasiddhāntikā* (about 570 A.D., Varāhamihira died in 587 A.D.). The original *Sūrya-siddhānta* was prior to Varāhamihira, the modern edition is perhaps of the 13th century. See J. Burgess "Notes on Hindu Astronomy," J. R. A. S., October 1893, p. 742.

Earth as a Sphere

The astronomers of the *Siddhāntas* taught that the Earth is a sphere, unsupported in space, and they reject the ancient mythological notion that it is supported by some animal like śeṣanāga (serpent), kacchapa (tortoise), or diggajas (elephants) which in turn rest on another, and so on, until the support of the last one after all has to be left unexplained. Bhāskara II, about A.D. 1150, who comments on the absurdity of this, also rejects the idea that the Earth is perpetually falling, since it would fall faster than an arrow shot upwards, on account of being heavier, so that an arrow could never again reach the Earth.¹ Round the Earth the planets are moving, all with the same linear velocity. The diameter of the Earth is 1600 yojanas, the distance of the Moon is 51,570 yojanas (or 64.5 times the radius of the Earth, nearly equal to Ptolemy's greatest distance, $64\frac{1}{2}$), while the distances of the other planets result from the assumption of equal velocities.² The equation of centre of the planets is found by an epicycle and to this arrangement the Hindus add one of their own invention, by assuming that the epicycle had a variable circumference, greatest when the planet is at apogee or perigee and least at 90° from these, when the equation reaches its maximum. This contrivance of an oval epicycle was by some astronomers applied to all the planets, by others (Brahmagupta and Bhāskara) only to Mars and Venus, by others it was altogether rejected.³ Why they complicated the calculation in this way is not clear. Āryabhaṭa I of Kusumapura or Pāṭaliputra, born A.D. 476, made another deviation from the Alexandrian doctrines, as appears in the *Brāhma-sphuṭa-siddhānta* of Brahmagupta, wherein he quotes the following from Āryabhaṭa: "The sphere of the stars is stationary, and the Earth, making a revolution, produces the daily rising and setting of stars and planets." Brahmagupta rejects this idea, saying: "If the Earth moves a minute in a prāṇa, then whence and what route does it proceed? If it revolves, why do not lofty objects fall?" But his commentator Caturveda Pṛthudaka Svāmi replies: "Āryabhaṭa's

1. *As. Res.* XII. p. 229 (*Essays*, II, p. 394).

2. The distances are proportional to the orbital periods of revolution, but for Mercury and Venus to the periods in the epicycles.

3. For further details see *As. Res.* II. p. 251 (Davis) and XII. p. 236 (Colebrooke, also *Essays*, II, p. 401).

opinion appears nevertheless satisfactory, since planets cannot have two motions at once : and the objection, that lofty things would fall, is contradicted; for every way the under part of the Earth is also the upper; since wherever the spectator stands on the Earth's surface, even that spot is the uppermost spot.¹

Earth rotation by a current of aerial fluid

It is very interesting to see the theory once advocated by Herakleides of Pontus transplanted on Indian soil, especially when we remember that Seleukus, the Babylonian, had adopted that theory. From Babylon the theory might easily find its way to India, though it is of course equally possible that Āryabhata, quite independently of his Greek precursors, hit on the same idea. He appears to have accounted for the Earth's rotation by a wind or current of aerial fluid, the extent of which, according to the orbit assigned to it by him, corresponds to an elevation of little more than a hundred miles (114) from the surface of the Earth, or fifteen *yojana*'s while he put the diameter of the Earth equal to 1050 *yojanas* (of 7.6 miles each²). This was in accordance with the general opinion of the Indians, that the planets are carried along their orbits by mighty winds with the same velocity and parallel to the ecliptic (while one great vortex carries all stars round the Earth in twenty-four hours, but that the planets are deflected from these courses by certain invisible powers having hands and reins, with which they draw the planets out of their uniform progress. The power at the apogee, for instance constantly attracts the planet towards itself, alternately with the right and left hand (like Lachesis in Plato's *Republic*), while the deity at the node diverts the planet from the ecliptic first to one side and then to the other. And lastly the deity at the conjunction causes the planet to move with variable velocity and to become occasionally stationary and even retrograde. This is gravely set forth in the *Sūrya-siddhānta*, and even Bhāskara gives the theory in his notes, though he omits it from his text. Similarly Brahmagupta, although he gives the theory of eclipses, affirms the existence of an eighth planet, Rāhu, which is the immediate cause of eclipses; and he blames Varāhamihira,

1. *Asiat. Res.*, XII, p. 227; Colebrooke's *Essays*, II, p. 392.

2. Colebrooke, *Notes and Illustrations to the Algebra of Brahmagupta*, p. xxxviii. *Essays*, II, p. 467.

Āryabhaṭa and others for rejecting this orthodox explanation of the phenomenon.¹

Indian astronomy some times appears to be a curious mixture of old fantastic ideas and sober geometrical methods of calculation. But it is wrong to presume that these geometric calculations were derived from foreign contacts. Indians have always been fond of geometry (from the earliest times of the Vedic rituals), and they from the very beginning realised the importance of applying geometry to astronomy. Side by side we find Greek contacts also. As remarked by Colebrooke, the absence of the most characteristic parts of Ptolemy's system, the equant and the details of the theories of the Moon and Mercury seems to indicate that Greek planetary theory must have been introduced in India between the times of Hipparchus and Ptolemy; and with the exception of the epicycle from the circular form, the Hindus did not modify the theory or perfect it in any way. The precession of the equinoxes they held to consist in a liberation within the limits of 27° (Āryabhaṭa says 24°) east and west of its mean position, but they came much nearer to the truth than Ptolemy did as regards the annual amount, as they supposed the space travelled over in a century to be $1\frac{1}{2}^\circ$.

Contacts with Arabs

Notwithstanding some isolation of India from Europe during the Middle Ages, her astronomy was destined to exercise an indirect influence on the progress of astronomy. Through the conquest of Persia in the seventh century, the Arabs, like the Greeks a thousand years earlier, came in contact with India, from whence physicians and astrologers found their way to the court of the Caliph already before the reign of Harun al Rashid. We possess a detailed account of the manner in which the Indian astronomy was introduced at Baghdad, from the pen of the astronomer Ibn al Adami (who died before 920), confirmed by the celebrated memoir on India by Al Beruni, written in 1031². In the year 156 of the Hījra (A. D. 773), there appeared before the Caliph Al Mansur a man who had come from India; he was skilled in

2. Hankel, *Zur Geschichte der Mathematik im Alterthum und Mittelalter*, Leipzig, 1874, p. 229; Cantor, *Gesch. d. Math.* I, p. 656.

the calculus of the stars known as the *Sindhind* (i. e. *Siddhānta*), and possessed methods for solving equations founded on the *kardagas* (i. e. *kramajyā*, sines) calculated for every half degree, also methods for computing eclipses and other things. Al Mansur ordered the book in which all this was contained to be translated into Arabic, and that a work should be prepared from it which might serve as a foundation for computing the motions of the planets. This was accordingly done by Muhammed ben Ibrahim Al Fazari, whose works the Arabs call the great *Sindhind*, and from it an abstract was afterwards made for Al Mamun by Abu Giafar Muhammed ibn Musa al Kwarizmi, who made use of it to prepare his tables, which obtained great renown in the lands of Islam. But when Al Mamun became Caliph, he promoted these noble studies and called in the most learned men in order to examine the *Almagest* and make instruments for new observations.

Arabs and Greeks

The account of which the above is an abstract shows us clearly the origin of the study of astronomy and mathematics under the Abbasid Caliphs. But though the first impulse came from India the further development of Arabian science was to a considerable extent founded on that of Greece and Alexandria. It was through the court physicians from the flourishing medical school kept up by Nestorian Christians of Khusistan that a knowledge of Greek Philosophy and science was first spread among the subjects of the Caliphs; and by degrees the works of Aristotle, Archimedes, Euclid, Apollonius, Ptolemy, and other mathematicians were translated into Arabic. Fresh translations of Ptolemy were made from time to time in the various kingdoms into which the vast empire of the Caliph was soon split up,¹ and a thorough knowledge of Ptolemaic astronomy was thus spread from the Indus to the Ebro. There were several special inducements for Muhamedans to pay attention to astronomy, such as the necessity of determining the direction in which the

1. The earliest is probably that of Al Haggag ben Jusuf ben Matar early in the ninth century. See Suter, *Die Mathematiker und Astronomen der Araber und ihre Werke*, Leipzig, 1900 (p. 9), which valuable bibliographical summary has been followed by J. L. E. Dreyer as regards names and dates (J. L. E. Dreyer's *A History of Astronomy*, 1953; we have reproduced this account from his chapter XI.)

faithful had to turn during prayers, also the importance of the lunar motions for the calendar, and the respect in which judicial astrology was held all over the East. The Caliph Al Mamun, son of Harun Al Rashid (813-833) is the first great patron of science, although the Omayyad Caliphs had much earlier an observatory near Damascus, and the Jew Mashallah (who died about 815) had already before the reign of Al Mamun won a name as an observer and astrologer. But the Damascus observatory became quite eclipsed by that erected at Baghdad in 829 where continuous observations were made and tables of the planetary motions constructed while an important attempt was made to determine the size of the Earth. Among the astronomers of Al Mamun and his successors one of the greatest was Ahmed ben Muhammed Al Fargani (afterwards known in the West as Alfraganus), whose *Elements of Astronomy* were translated into Latin in the twelfth century and contributed greatly to the revival of science in Europe.¹ Tabit ben Korra (826-901) was a most prolific writer and translator, but is chiefly known in the history of astronomy as a supporter of the erroneous idea of the oscillatory motion of the equinoxes. A younger contemporary of his, Muhammed Al Battani (died 929), was the most renowned of all the Arabian astronomers and became known in the West in the twelfth century (under the name of Albategnius) by the translation of the introduction to his tables.² Already in his time the power of the Caliphs had commenced to decline, and they soon lost all temporal power. The study of astronomy was, however, not influenced by this loss of patronage, as the Persian family of the Buyids, who in 946 obtained possession of the post of Amir-al-Omara (corresponding to the Frankish Major Domus) took over the rôle of patrons of science, so long and so honourably carried on by the Abbasid Caliphs. Sharaf al Daula built in 988 a new observatory in the garden of his palace, and among the astronomers who worked there was Muhammed Abu 'I Wefa al Buzjani (959-998), who wrote an *Almagest* in order to

1. First printed at Ferrara in 1493. See the edition of Golius, Amsterdam, 1669.

2. Translated by Plato of Tivoli. First Printed in 1537 after the book of Alfraganus. Dreyer has used the edition of Bologna, 1645, and a new edition which is now being published by C. A. Nallino, of which the Arabic and a Latin translation of the text have already appeared (*Publ. d. R. Osservatorio di Brera in Milano*, No. 40, 1899-1903).

make the contents of Ptolemy's work accessible to the less learned. In the nineteenth century this book gave rise to a long controversy, which we shall presently consider somewhat in detail.

Western Countries under Islam

In the eleventh and twelfth centuries we do not find any names of conspicuous astronomers in Muhammedan Asia. But the western countries under Islam had in the meantime become ready to do their share of the work of keeping the mathematical sciences alive. In the Fatimite kingdom of Egypt Ali ben Abi Saïd Abderrahman ben Ahmed ben Jūnis, generally called Ibn Jūnis (died 1009), was distinguished both as an astronomer and a poet. At Cairo a liberally equipped observatory enabled him to verify the planetary theories which had once been developed in the neighbouring Alexandria, and in token of his gratitude to the reigning sovereign, Al Hakim, he named his work the *Hakemite Tables*.¹ We have to pass to the farthest west to find the next astronomer of mark in the person of Ibrahim Abu Ishak, known as Al Zarkali (in Europe afterwards called *Arzachel*). He was a native of Cordova, lived about 1029-1087, and edited planetary tables called the *Toledo Tables*.² In the following century we find two celebrated astronomers of Seville, Gabir ben Aflah, known as Geber (died 1145, often mistaken for the great alchemist, Gabir ben Haijan, in the eighth century),³ and Nur ed-din al Betrūgi (*Alpetragius*), both of whom raised objections to the planetary theories of Ptolemy, though they failed to produce anything better of their own. Spanish astronomy continued to flourish for a while, although the power of the Arabs in the Peninsula was rapidly declining, and it produced in the thirteenth century a very remarkable man, who, although a Christian king, must be included in this account of Arabian astronomy.

 3. The word algebra has also sometimes erroneously been connected with his name.

as he owed all he knew about the science to the example and the teaching of Muhammedans and Jews. King Alfonso X, of Castille named elSabio (1252-1284), followed the example of the Caliphs and called astronomers to his court to assist in the preparation of the renowned Alfonsine Tables.

With Alfonso the study of astronomy disappeared from Spain, but not before it had been revived in the East. In 1258 the still existing but shadowy Caliphate of Baghdad was swept away by the Mongol conqueror Hulagu Khan, grandson of Genghis Khan; but already in the following year this great warrior listened to the advice of his new vazier, Nasir ed-din al Tusi (born at Tūs in Khorasan in 1201, died in 1274), and founded a great and magnificent observatory at Merāgha, in the north-west of Persia. In this observatory, which was furnished with a large number of instruments, partly of novel construction, Nasir ed-din and his assistants observed the planets diligently and produced after twelve years labour, the "Ilokhanic Tables." Among the astronomers of Merāgha seems to have been Juhanna Abu 'l Faraj, called Bar Hebrāyā, or the son of a Jew. He was a Christian, born in 1226 and from 1264, till his death in 1286 Maphrian or Primate of the Eastern Jacobites. He left a well-known chronicle and an astronomical work, both written in Syriac, as well as other writings.¹ The observatory at Merāgha had not a long life, and Asiatic astronomy had to wait a century and a half, until the grandson of another terrible conqueror erected another observatory. Ulug Begh, grandson of Tamerlan, drew learned men to Samarkand and built an observatory there about the year 1420, where new planetary tables and a new star catalogue, the first since Ptolemy's, were prepared. Ulug Begh died in 1449, he was the last great Asiatic protector of astronomy; but just as the Eastern countries saw the star of Urania setting, it was rising again for Europe.

In this review of Arabian astronomers we have only mentioned a few, omitting several names of distinction, whose

1 *Le livre de l' ascension de l' esprit sur la forme du ciel et de la terre. Cours d' Astronomie redigé en 1279 par Gregoire Aboulfarag, dit Bar Hebraeus. Publié par F. Nau, Paris, 1899-1900 (2 parts, Syriac and French). His chronicle is the chief authority for the fable about the burning of the Alexandrian Library by order of the Caliph Omar. For a very thorough refutation of this see Burier, *The Arab Conquest of Egypt*, Oxford, 1902 pp 401-426.*

owners devoted themselves to other branches of astronomy. Though Europe owes a debt of gratitude to the Arabs for keeping alive the flame of science for many centuries and for taking observations, some of which are still of value, it cannot be denied that they left astronomy pretty much as they found it. They determined several important constants anew, but they did not make a single improvement in the planetary theories. It will therefore be sufficient to enumerate the improvements attempted and the opinions held by Arabian astronomers without keeping strictly to the chronological order, although we are here dealing with a period of about six hundred years and men belonging to very different nations, who had little in common except their religion and the language in which they wrote.

Figure of Earth

Turning first to the question of the figure of the Earth, we find a remarkable contrast between Europe and Asia. In the world under Islam there was an entire absence of that hostility to science which distinguished Europe during the first half of the Middle Ages. Though we learn from Kazwini's *Cosmography*¹ that some of the earlier Arabs believed the Earth to be shaped like a shield or a drum, still there is no record of any Arabian having been persecuted for asserting that the Earth is a sphere capable of being inhabited all over. Whether this was in consequence of the warriors of the Caliphs having carried their arms to the centre of France on one side and to the borders of China on the other while their merchants travelled southward to Mazambique and northward to the centre of Asia, is another question : anyhow, the fact of the Earth being a sphere of very small dimensions in comparison to the size of the universe was accepted without opposition by every Arabian scholar, and the very first scientific work undertaken after the rise of astronomy among them was a determination of the size of the Earth. It was carried out by order of the Caliph Al Mamun in the plain of Palmyra. According to the account given by Ibn Junis, the length of a degree was measured by two observers between Wamia and Tadmor and by two others in another locality, we are not told where. The first measure gave a degree

1. Zakarija Ben Muhammed Ben Mahmūd El Kazwini's *Kosmographie*, deutsch von H. Erbe, Leipzig, 1868, p. 295.

equal to 57, the second one equal to $56\frac{1}{2}$ Arabian miles of 4000 black cubits, and the approximate mean, $56\frac{2}{3}$ miles, was adopted as the final result, the circumference of the Earth being 20,400 miles and the diameter 6500 miles. Another report, by Ahmed ben Abdallah, called Habash, an astronomer under Al Mamun (quoted by Ibn Junis), states that a party of observers (no names given) proceeded along the plain of Sinjar until they found a difference in meridian altitudes, measured the same day, equal to one degree, while the distance travelled over was found to be $56\frac{1}{2}$ miles¹. Probably two different determinations were made. If the "black cubit" is the Egyptian and Babylonian cubit of 525 mm.², the mile would be=2100 m. and $56\frac{2}{3}$ miles=119,000 meters, rather a large result.

The doctrine of the spherical earth remained undisputed in the Muhammedan learned world, though the curious error of assuming that the level of the sea was higher on some parts of the Earth than on others appears to have found some adherents among Arabian writers as well as in Europe.³ We may, therefore, at once pass on to the motions of the heavenly bodies. Al Battani determined the longitude of the Sun's apogee and found it=82° or 16° 47' more than Ptolemy had given. As he believed

1. Caussin, *Not. et Extraits*. vii. pp. 94-96; Delambre, *Hist. de l'astr. du Moyen Age*. pp. 78 and 97; Shems ed-din, *Manuel de la cosmographie*, traduit par Mehren, Copenhagen. 1874 p. 6. Suter, p. 209, mentions a third report (from Ibn Challikan's *Biographical Dictionary*), according to which the sons of Musa first measured in the plain of Sinjar and afterwards as a test at Kufa, by order of Al Mamun. The eldest of the sons of Musa died 41 years after Al Mamun, and the names of the observers in the first report are different, so that the third report is not to be relied on. Al Fargani merely gives $56\frac{2}{3}$ miles as the result of Al Mamun. According to Shah Cholgii *Astronomica . . . studio et opera Joh. Gravii*, London, 1652, p. 95, Ala ed-din Al Kusgi (one of the Ulug Begh's astronomers) gives the circumference of the earth=8000 parasangs. As a persian parasang =30 stadia (Hultsch; *Griech u. Rom. Metrologie*. p. 476) this would seem to be the value of Posidonius, 240,000 stadia. Kazwini (p. 298) gives the circumference=6800 parasangs on the authority of Al Beruni.
2. Hultsch p. 390.
3. It deserves to be mentioned that Shems ed-din of Damascus (1256-1327) explains the great Preponderance of dry land in the northern hemisphere by the attraction of the Sun on the water, which is the greatest when the Sun is in perigee, at which time it is nearly at its greatest south declination. That this accumulation of water would not be a permanent one does not occur to him (*Cosmographie*, p. 4).

that Ptolemy's value had been found by himself,¹ and as he adopted $54''$ (or 1° in 66 years) as the annual amount of precession, there remained (assuming that 760 years had passed since the time of Ptolemy) an outstanding error of $79'' - 54'' = 25''$ per annum. In reality the annual motion of the solar apsidal is $11\frac{1}{2}''$; still we may say that the discovery of this motion is due to Al Battani, though he did not announce it as such; in fact he merely gives his own value as an improvement on that of Ptolemy. Even Ibn Junis (who found $86^\circ 10'$) did not suspect that the apogee was steadily moving but merely says that it must be corrected for precession (1° in 70 years), and remarks that the longitude of the apogee is very difficult to determine accurately.² On the other hand, Al Zarkali found a smaller value, $77^\circ 50'$ and as he also found a smaller value of the eccentricity he thought it necessary to let the centre of the Sun's eccentric orbit describe a smaller circle, after the example set by Ptolemy in the case of Mercury.³ The inclination of the ecliptic which the Greeks had found— $23^\circ 51' 20''$ was by the astronomers of Al Mamun found— $23^\circ 33'$ (in 830), by Al Battani (in 879), and by Ibn Junis $23^\circ 35''$.⁴ When Al Zarkali found $23^\circ 33'$, he, and afterwards Abu 'l Hassan Ali of Morocco, concluded that the obliquity oscillated between $23^\circ 53'$ and $23^\circ 33'$, an idea to which the prevailing belief in the "trepidation" of the equinoxes lent countenance.⁵

Moon and its orbit

If we now turn to the Moon, we do not find that the Arabs made any advance on Ptolemy. Several of them noticed that the inclination of the lunar orbit was not exactly 5° , as stated by Hipparchus. Thus, Abu 'l Hassan Ali ben Amagiur early in the tenth century says that he had often measured the greatest latitude of the Moon and found results greater than that

1. *Scient. Stell.* Cap. xxviii. Bologna, 1645, p. 72; Nallino. p. 44. At the end of Cap. xlv. he says the apogees of the Sun and Venus are both in $82^\circ 14'$, and Ibn Junis also gives $82^\circ 14'$ as the value found by Al Battani (Caussin, p. 154).
2. Caussin, pp. 232 and 238. Abu'l Faraj gives $89^\circ 28'$ for the year 1279 (p. 22).
3. Sedillot, *Prolegomenes aux tables astron. d'Olough Beg* (1847), pp. lxxx-lxxxii. Riccioli, *Almag. Novum*, I. p. 157.
4. Caussin. p. 56. For A.D. 900 Newcomb gives $23^\circ 34' 54''$, with a diminution of $46''$ per century, so that the Arabian astronomers erred less than $1'$.
5. Aboul Hassan Ali, *Traite des Instruments astron. des Arabes*. T.I.p. 175; Sedillot, *Memoire sur les instr. astr. des Arabes*, p. 32.

of Hipparchus, but varying considerably and irregularly. Ibn Junis, who quotes this, adds that he has himself found $5^{\circ} 3'$ or $5^{\circ} 8'$, while other observers are said to have found from $4^{\circ} 58'$ to $4^{\circ} 45'$.¹ Want of perseverance and of accurate instruments caused them to miss a remarkable discovery, that of the variation of the lunar inclination.

Abu 'l Wefa and his *Almagest*

But an even more remarkable discovery has been claimed for an Arabian astronomer. In 1836 the younger Sedillot announced that he had found the third inequality, the variation, distinctly announced in Abu 'l Wefa's *Almagest*. A fierce controversy raged for a number of years as to the reality of this discovery, Sedillot alone defending his hero with desperate energy and refusing to listen to any arguments, while Biot, Libri and others as strenuously maintained that Abu 'l Wefa simply spoke of the second part of the evection, the *prosneusis* of Ptolemy. The fight had died out when, in 1892, Chasles suddenly took up the cudgels for Sedillot and pointed out what seemed to him to be some contradictions in Ptolemy's statement.² Nobody answered this until Bertrand did so in 1871; he called attention to several inaccuracies in the text of Abu 'l Wefa as we possess it now, and also showed that Abu 'l Wefa did not add his "mohazat" to the *prosneusis*, the latter not being included in his "second anomaly."³ It is unnecessary to enter into a more detailed account of the controversy; but to show that any weapon was considered good enough with which to defend Abu 'l Wefa, it may be mentioned that Sedillot and Chasles tried to prove that Tycho Brahe must have copied his discovery from Abu 'l Wefa, because he calls it *hypothesis redintegrata*. Tycho used this same phrase in speaking of his own planetary system, which he most emphatically claimed as

1. Sedillot, *Prolegomenes*, p. xxxviii. *Matériaux pour servir à l'hist. des sciences chez les Grecs et les Orientaux*, T. I. p. 283. The sons of Musā ben Sakir (about 850) seem to have been the first to find a value differing from that of the ancients. Abraham ben Chijsa, a Jewish writer who lived about A. D. 1100 says that Ptolemy found 5° , but that according to the opinion of the Ishmaelites it is $4\frac{1}{2}^{\circ}$ (*Sphaera mundi*, Basle, 1546 p. 102).
2. *Lettre à M. Sedillot sur la question de la variation lunaire*, Paris, 1862, 15 pp. 4° and *Comptes Rendus*, vol. 54, p. 1002.
3. *Comptes Rendus*, vol. 73, pp. 581, 756, 889; *Journal des Savants*, 11 Oct. 1871.

an original discovery, and which he vigorously defended against other claimants. In future it will be hopeless for anybody to claim the discovery for Abu 'l Wefa as the matter has now been thoroughly sifted, both by mathematicians and orientalists.

The *Almagest* of Abu 'l Wefa has never been published in full, but there are three translations of the chapters in question,¹ which only differ in some trivial points. In no part of the book does he make any advance on Ptolemy or claim to have made any new discovery, and in speaking of three inequalities he merely does what the other Arabian astronomers do.² He begins by describing the first (equation of the centre) and the second (evection) and states when they reach their maxima. He then says that we have found³ a third inequality, which takes place when the centre of the epicycle is between the apogee and the perigee of the eccentric, and which reaches its maximum when the Moon is about a *tathlith* or a *tasdis* from the Sun, while it is insensible in syzygy and quadrature. The maximum is $\frac{3}{4}^{\circ}$. He explains that this is caused by a deviation of the line or apsides of the epicycle, and he describes quite correctly the construction adopted by Ptolemy (whose name he does not mention), letting the line of apsides be directed, not to the Earth but to another point on the line of apsides of the eccentric. It is difficult for an unbiassed reader to understand how anyone could fail to see that Abu 'l Wefa is simply copying Ptolemy. Sedillot maintained that the words *tathlith* and *tasdis* mean the octants (where the variation reaches its maximum); but every other orientalist who has expressed an opinion, states that by their roots the words correspond to the numbers 6 and 3, in other words, to elongations 60° and 120° from the Sun. This is in accordance with

1. By Reinaud, Munk, and de Slane (for Biot) in the *Journal des Savants*, March, 1845 (14 pp. the whole section on the Moon) ; by Sedillot, *Matériaux*, i. pp. 45-49 ; and by Carra de Vaux, "L' almageste d' Abu 'l Wefa Albūzjdjani," *Journal asiatique*, 8^e Serie, T. xix. (1892), pp. 408-471 (translation on pp. 443-44). Most of the chapters on the planets are lost.
2. The unknown author of a short resume of astronomy (in the *Bibl. Nationale*) even calls the inequality of prosneusis the first equation (Carra de Vaux, l.c. p. 460). This is not unreasonable, since the equation of the centre must be taken from the lunar tables, using as argument not the mean anomaly but the latter corrected for the effect of the prosneusis.
3. He uses exactly the same expression when speaking of the first and second inequalities.

facts, as Biot has shown from the Ptolemy's numerical data that the deviation of the line of apsides reaches its maximum value of $\pm 13^{\circ} 8' .9$ in elongations $90^{\circ} \mp 32^{\circ} 57' .5$.¹ But it must be acknowledged that the words in question are also used very vaguely, e. g. by Abu 'l Wefa himself, who says that the velocity of the superior planets after emerging from the Sun's rays diminishes gradually till their distance from the Sun is about a *tathlith*, when they become stationary. It looks almost as if these words might be used to denote any elongation outside syzygy and quadrature.²

If Abu 'l Wefa had made a new discovery, we should have expected later Arabian astronomers to have alluded to it. But not one of them gives anything but interpretations of the lunar theory of Ptolemy, and in expressions very similar to those employed by Abu 'l Wefa. Attention was at once called to this fact, and Isaac Israeli of Toledo (about 1310) and Geber of Seville were quoted as examples,³ though it would, of course, have been quite possible for these two writers to have remained ignorant of whatever progress astronomy might have made in the school of Baghdad. But this objection does not apply to Nasir ed-din al Tusi, in whose review of the *Almagest* and *Memorial of Astronomy* the inequalities known to Ptolemy and no others, are described and credited to Ptolemy⁴; not to Mahamud al Jagmini (about 1300), who wrote a compendium (*mulachchas*)

1. *Journal des Savants*, 1843, p. 701 ("Sur un traite arabe relatif a l'astronomie," Reprint, p. 47). This deviation does not represent the amount of the correction to the Moon's place as seen from the Earth, so that there is not any contradiction in Ptolemy's account.
2. Carra de Vaux. l. c. p. 466. The Arabs had no word for "octants." Nasir ed-din on one occasion wants to mention them, and has to call them "the points midway between syzygy and quadrature."
3. Isaac Israeli repeatedly speaks of these inequalities discovered by Ptolemy, two of which are not found at conjunction and opposition. *Liber Jesod, Olam seu Fundamentum Mundi auctore R. Isaac Israeli Hispano*, section III. ch. 8 and sect. v. ch. 16, Part I. p. xxiv Part II. p. xxxi (Berlin, 1848 and 1846; this publication is not mentioned by Carra de Vaux).
4. C. de Vaux, "Les spheres celestes selon Nasir Eddin Attusi", Appendix to P. Tanhery's *Recherches sur l'astr. anc.* p. 342, and *Journ. asiat.* 1892, p. 459: "The third anomaly is that of the prosneusis; it is called the equation of the proper motion" (i.e. of the motion on the epicycle).

of astronomy.¹ Nor can any objection be raised to Abu'l Faraj (Bar Hebraeus), and it would be impossible to explain more clearly than he does the effect of the prosneusis. He says: "The third inequality is the angle formed at the centre of the epicycle by two lines which are drawn, one from the centre of the universe and the other from the point called the prosneusis, at the end of which is the apogee of the epicycle, at which commences the proper motion, and which is called the mean apogee. The apogee which is at the end of the line drawn from the centre of the universe is called the apparent one. The point prosneusis is on the side of the perigee of the eccentric, 10 parts 17 minutes from the centre of the world² which is itself at the same distance from the centre of eccentric. The maximum value of this angle is 13 parts 9 minutes when the Moon is a crescent or $\frac{3}{4}$ gibbous, that is, near the hexagon or trigon with the Sun. In fact, when the epicycle is four or eight signs distant from the apogee of the eccentric, the Sun is itself two or four signs distant from [the centre of the epicycle] because it is half way between this centre and the apogee. In the tables, this inequality of the two apogees is called the first angle and is included in the motion of the centre."³ While this describes the construction of Ptolemy as clearly as possible, at the same time the agreement of the account with that of Abu'l Wefa is perfect. Abu'l Faraj even (like Nasir ed-din) describes as a fourth inequality in longitude that caused by the motion along an orbit inclined to the ecliptic, so that he would not have neglected to describe the variation, if it had been found by an astronomer of Baghdad. We may add that the Jewish writer Abraham ben Chija (A. D. 1100), in his *Sphaera Mundi*, also describes the "aberration" of the apside of the epicycle, chiefly "in sexta et tertia parte mensis."⁴

1. Translated by Rudloff and Hochheim, *Zeitschrift der Deutschen Morgenland Ges.* XLVII pp. 213—275. He describes (p. 249) how the line of apsides is directed to a point called "the corresponding point," and gives its position correctly. The inequality he calls the deviation.
2. Nasir ed-din gives 10° 9'.
3. *Le livre de l' ascension*, & c. T. II. PP. 29-30. Two codices add after the word prosneusis: "This is the point mohazat."
4. *Sphaera Mundi* (1546, ed. Schreckentuchs), p. 75. Munster's commentary to the Hebrew text (p. 116) has "cum centrum est in sextili aut trino aspectu [id est, quando abest a sole duobus signis aut quatuor]"; the words in brackets are not in the Hebrew original. The words "sixth" and "third" are unmistakable (shithith and shelishith). Apparently no one has hitherto thought of consulting Abraham ben Chija.

Abu 'l Wefa and Ptolemy

Therefore, Abu 'l Wefa did not know a single thing about the motion of the Moon which he had not borrowed from Ptolemy. But the prosneusis of Ptolemy is not the variation discovered by Tycho Brahe. The latter depends solely on the elongation of the Moon from the Sun, as it is $= +39' .5 \sin 2\varepsilon$, while it is beyond the power of mortal man to express the effect of the prosneusis without the anomaly. Ptolemy's expression for all the inequalities in longitude assumed by him, when developed analytically, found to contain, in addition to terms representing the equation of the centre and the evection, the latter being

$$+1^{\circ}19'.5 \sin (2\varepsilon - m),$$

a very considerable term

$$+17.8 \sin 2\varepsilon [\cos (2\varepsilon + m) + 2 \cos (2\varepsilon - m)],$$

where ε is the elongation and m the mean anomaly.¹

Obviously this term has nothing in common with the variation, except that it disappears in the syzygies and quadratures. Tycho Brahe did not hang his new term on to the unaltered lunar theory of Ptolemy, and by doing that we should in fact only spoil the latter and make its maximum error rise to more than a degree.² Owing to the insufficiency of the observations at his disposal, Ptolemy could only perceive that there was some outstanding inequality after allowing for the evection, only appearing outside the syzygies and quadratures, but he was neither able to find the law which governed the phenomenon, nor was he aware what a large quantity it represented; he could only tinker up his constructions a little, and in this he was most faithfully followed by the Arabs, who added nothing to what he had done and left it to the reviver of practical astronomy to discover the third lunar inequality.

Al Fargani and others on Planets

Passing to the five planets, we find that, generally speaking, very few attempts were made to improve the work of Ptolemy. But the Arabs were not content to consider the Ptolemaic system

P. Tannery, *Recherches*, p. 213. Another expansion of Ptolemy's lunar inequalities in a series was given by Biot, *Journal des Savants*, 1843, p. 703 (Reprint, p. 49).

P. Kempf, *Untersuchungen über die Ptolemaische Theorie der Mondbewegung*, Berlin, 1878 (Inaug. Diss.), p. 37.

merely as a geometrical aid to computation; they required a real and physically true system of the world, and had therefore to assume solid crystal spheres after the manner of Aristotle. Above the Moon is the Alacir, the fifth essence, which is devoid of lightness and heaviness, and is not Perceptible to the human senses; of this substance the spheres and planets are formed.¹ Already in the book of Al Fargani we find the principle adopted which we have seen dates from the fifth century (Proklus) and which became universally accepted in the Middle Ages, that the greatest distance of a planet is equal to the smallest of the planet immediately above it, so that there are no empty spaces between the spheres.² The semidiameter of the Earth is by Al Fargani given as 3250 miles, which corresponds very nearly to Al Mamun's $56\frac{2}{3}$ miles to a degree, if we put $\pi = \frac{22}{7}$. Starting from Ptolemy's distances of

Greatest Distance of	Al Fargani	Al Battani	Abu 'l Faraj ³
Moon	64 $\frac{1}{2}$	64 $\frac{1}{2}$	64 $\frac{1}{2}$
Mercury	167	166	174
Venus	1,120	1,071	1,160
Sun	1,220	1,146 ⁴	1,260
Mars	8,876	8,022	8,820
Jupiter	14,405	12,924 ⁵	14,259
Saturn	20,110	18,094	19,963

the Moon and the Sun, it was easy to express the other distances in semidiameters of the Earth, the ratios between the greatest and

1. Al Battani, cap. 50 (p. 195).
2. Al Fargani, cap. 21 (ed. Golius, p. 80). Much later, Maurolycus in his *Cosmographia* (Venice, 1543, f. 20a) proves that Mercury and Venus must be below the Sun, by pointing out that there would otherwise be a large vacant space between the Sun and the Moon.
3. pp. 189-191.
4. So in Nallino's ed. (Milan, 1903 p. 121) the ed. of 1645 has 1176.
5. The ed. of 1645 has 12, 420; obviously an error, as the ratio of greatest to smallest distance is given as 37:23 for Saturn 7:5 (misprinted 7:2), or "quantitas unius et duarum quintarum ad unum" (p. 199). Nallino's ed (Milan 1903) has 12,924. Abraham ben Chija has 12,400.

smallest distances being in substantial agreement with the theory of Ptolemy. Al Battani also gives a similar set of figures, though with some slight differences. He does not mention peculiar treatment given by Ptolemy to the theory of Mercury. The above table gives the distance expressed in semidiameters of the Earth.

Al Kūsgi and diameters of planets

Al Kūsgi, one of the astronomers of Ulug Begh, gives a list of the semidiameters of the "concavities" of the planetary spheres (i.e. the smallest distances of the spheres) expressed in parasangs, the diameter of the Earth being 2,545 parasangs.¹ Expressed in semidiameters of the Earth, the figures turn out somewhat different from those given above, e.g. the smallest distance of the Sun being 1,452 and the greatest of Saturn 26,332, but he does not supply any means of making out how these figures were found.

Before leaving this subject, we shall also give the diameters of the planets according to Al Fargani, as they became known in Europe at an early date and were quoted by Roger Bacon and others.² With trifling variations the same values are given by Al Battani, Abu 'l Faraj, and Abraham ben Chija.

	Apparent Diameter	True Diameter (Earth's=1)
Moon in apogee	$31\frac{1}{2}'$	$1 : 3\frac{1}{2}$
Mercury, mean dist.	$\frac{1}{18}$ of Sun's	$\frac{1}{18}$
Venus " "	$\frac{1}{6}$ " "	$1 : 3\frac{1}{2}$
Sun " "	$31\frac{1}{2}'$	$5\frac{1}{2}$
Mars " "	$\frac{1}{10}$ of Sun's	$1\frac{1}{2}$
Jupiter " "	$\frac{1}{12}$ of Sun's	$4\frac{1}{2} + \frac{1}{12}$
Saturn " "	$\frac{1}{18}$ " "	$4\frac{1}{2}$

Al Kazwini, Abu'l Faraj and

Al-Jagmini on Excentric Spheres of the Sun

The system of the spheres is set forth in greatest detail in three treatises of later date, the cosmography of Zakarija ben Muhammed ben Mahmud al Kazwini (about 1275), the astronomy

1. *Astronomica Shah Chelgii*, pp. 95-97.

2. There are some slight differences between the figures given in the various editions (J.L.E. Dreyer has compared those of 1493, 1546, and 1669), but those given above agree with the cubic contents according to Al Fargani. The figures of Kazwini seem to have been greatly corrupted.

of Abu 'l Faraj, written in 1279, and that of Mahmud ibn Muhammed ibn Omar al Jagmini, whose date and nationality are equally uncertain, but who probably wrote in the thirteenth or fourteenth century. We find in these text-books an elaborate system of spheres designed to account for every particular of planetary motion, in perfect agreement with each other as to the general arrangement of the spheres, and offering nothing new as to lunar or planetary theory. The accompanying figures (taken from Jagmini) will illustrate the ideas better than a lengthy description.¹ The Sun is a solid sperical body, fitting between two excentric spherical surfaces, which touch two other surfaces, in the

Fig. 1.—Planetary motions and system of spheres.

5. Centre of the world. 6. Centre of the excentric sphere.

common centre of which the Earth is situated, and which between them enclose a space (or intersphere, as Abu 'l Faraj calls it), named by Jagmini al-mumattal, or the equably turning sphere, which has the same motion from west to east as the fixed stars, i.e. precession. The spheres of the three outer planets and Venus are arranged on the same plan, except that the place of the body of the Sun is taken by the epicycle-sphere of each planet, to the inner surface of which the planet (a solid spherical body) is attached or (as Abu 'l Faraj says²) "fixed like a pearl on a ring, touching the

1. Al Kusgi gives very similar diagrams of the spheres of the Saturn, Mercury, and the Moon.
 2. Precession is supposed to be included in this, "the first motion." The second
- (Continued on next page)

surface in one point." The axis of the excentric sphere is inclined to that of the mumattal sphere, which causes the motion in latitude. The lunar system comprises an additional sphere outside the others, the centre of which coincides with the centre of the world, and which is called *al-gauzahar*, signifying the constellation

tion Draco, as this sphere provides for the revolution of the lunar nodes ("the head and tail of the dragon") round the zodiac. The inner one of the two concentric spherical surfaces, between which the excentric sphere lies, surrounds immediately the fire sphere of the Earth. The system of Mercury is more complicated, as a space had to be provided for the revolution of the centre of the

(Continued from previous page)

one is that of the concentric oblique intersphere (called the mail sphere or the *sphaera deflectens*) round the centre of the world, $11^{\circ}9'$ per day, by which amount the lunar apogee moves towards the west. The third motion is that of the excentric, carrying the centre of the epicycle $24^{\circ}22'$ towards the east. The fourth is the motion on the epicycle. Abu 'l Fazar, p. 27.

excentric sphere. The figure shows the excentric sphere enclosed in a sphere, *al-mūdir* or the turning one, which allows the upper apsis or apogee of the excentric or deferent sphere (3 in the figure) to move right round the outer surface of the *mūdir*. The inner surface of the *mumattal* sphere immediately surrounds the *gauzahar* sphere of the Moon.

It was a necessary consequence of the large solar parallax of 3' accepted by Ptolemy, that Mercury and Venus must be very near the Earth, since they are assumed to be nearer than the Sun. Thus Abraham ben Chija says that the shadow of the Earth extends beyond the orbit of Mercury but does not reach that of Venus.¹ Ptolemy never mentions the parallaxes of Mercury and Venus, as to which nothing was known, though they ought, of course, to be greater than 3'. But on the assumption that the smallest distance of Mercury is equal to the distance of the Moon at apogee, the parallax of Mercury ought to rise to 54', which must have been felt to be too large a quantity, though it does not seem to have struck Al Battani as anything surprising, perhaps because Mercury cannot be seen when in inferior conjunction. It may have been this necessarily large parallax of Mercury, which induced Ibn Jūnīs (without any explanation) to reduce the solar parallax from 3 to 2', or rather to 1' 57".² Geber³ blames Ptolemy for having said that the parallaxes of the planets are insensible, and remarks that he ought, therefore, logically to have placed Venus and Mercury above the Sun. He takes great pains to show that Venus may be exactly on the line joining the Sun and the Earth. Indeed, Geber neglects no opportunity of criticising Ptolemy's methods of finding the elements of the orbits,⁴ and he is generally very unjust to him but he does not venture to

4. See the long indictment on pp. 2-3 of his introduction. He blames Ptolemy among other things for assuming that the centre of the deferent is half-way between the centres of the zodiac and of the equant, while he himself deduces this from the movements.

substitute any other system and does not object to the general principles of the Ptolemaic system.¹

Three great names :

Ibn Badja, Ibn Tofeil (Abubacer) and Abu Welid (Averroes)

Geber's attempts to pick holes in the work of Ptolemy were, perhaps, not unconnected with the rapid rise of Aristotelean philosophy in Spain in the twelfth century, which, though not destined to last long, nevertheless exercised a considerable influence on the spread of knowledge of Aristotle in the Christian world, while it cast a halo round the Caliphate of Cordova, which at that time, under the enlightened rule of the Almohades, seemed to have reestablished the glory of the best days of the Moslem world. Three names are specially associated with this movement :

- (i) Abu Bekr Muhammed Ibn Jahya al Sayeg, called Ibn Badja (of Saragossa, died 1139), known as Avempace among the Scholastics ;
- (ii) his pupil Muhammed ben Abdelmelik Ibn Tofeil (of Granada, died 1185-1186), called Abubacer by the Scholastics ;
- (iii) and finally the greatest philosopher of Islam, Ibn Rosd Abu Welid, known as Averroes (1126-1198).

In studying Aristotle they laid special stress on his scientific works, and did not, like their Christian successors, think of little but dialectics. The acceptance of the system of homocentric spheres or some modification of it must, therefore, have seemed a necessity to the Arabian philosophers and this, of course, led them to reject the theory of epicycles. The little we know of the opinions of Ibn Badja on this subject is found in the famous work *The Guide of the Perplexed* of the great Jewish scholar Moses ben Maimun of Cordova, better known as Maimonides, who tells us that he had his information from a pupil of Ibn Badja. Like Geber (with whose son he had been familiar), Maimonides doubted that Mercury and Venus were nearer than

1. Copernicus possessed a copy of Geber's book; which is now in the University library at Upsala. On the title page, after the author's name, he has written : "Egregii, Calumiatoris Ptolemaei," while a number of marginal notes show that he has read the book carefully. Curtze, *Mittheilungen des Copernicus Vereins*, I, p. 37.

the Sun, though he would not venture to say how they actually moved.¹ But what is more important, he declared the motion of a planet on an epicycle to be contrary to physical principles, because there are only three motions possible in this world : around its centre, or towards it, or away from it; while he also maintained that according to Aristotle circular motion can only take place round a real, central body.² Though Aristotle in reality did not object to epicyclic motion with a mathematical point as centre, for the simple reason that it had not been proposed when he wrote, while, as we have seen, his moving principle had nothing to do with the centre of motion, it is easy to see that Ibn Badja's real difficulty was the same which afterwards produced so many obstacles to the advance of science in Europe : whatever could not be found in Aristotle's book must be unworthy of notice. According to Maimonides (who, however, makes the reservation that he had not heard it from disciples), Ibn Badja constructed a system of his own, in which he only admitted excentric circles but no epicycles. We are not given any particulars as to this system but there can hardly be any doubt that its author confined himself to generalities and did not attempt to represent phenomena like the lunar inequalities by it. Maimonides remarks that there is nothing gained by Ibn Badja's reform, since the excentric hypothesis is as objectionable as the epicyclic one, as it also supposes motion round an imaginary point outside the centre of the Earth. The centre of the excentric, on which the Sun is supposed to move, is outside the convexity of the lunar sphere and inside the concavity of that of Saturn's excentric is between the spheres of Mars and Jupiter. He adds that the revolution of a number of concentric spheres around a common axis is conceivable, but not the revolution round different axes inclined to each other, as the spheres would disturb each other unless there are other spherical bodies between them. This attempt to revive and modify the system of (movable ?) excentrics did, therefore, not mend matters.³

2. *Ibid.*, Pars II, cap. XXIV.
3. Maimonides also remarks (in the same chapter) that the supposed inclinations of Mercury and Venus in the Ptolemaic system are difficult or impossible to comprehend or imagine as really existing. Therefore, if what

(Continued on next page)

Ibn Tofeil

Ibn Tofeil, the second of the three Moslem philosophers of Spain, vizier and physician at the court of Jusuf ben Abd el Mumin of Morocco, seems to have walked in the footsteps of his master; but the only extant work of his, a kind of religious mystic romance about the emancipation of a soul from the trammels of this material world, does not give any clue to his ideas as to the planetary system. But Averroes, who also objected to the excentrics and epicycles says in his commentary to Aristotle's *Metaphysics* that Ibn Tofeil possessed on this subject excellent theories ², and Ibn Tofeil's pupil, the astronomer Al Betrugi, in the introduction to his theory of the planets, says of him: "You know that the illustrious judge Abu Bekar Ibn Tofeil told us that he had found an astronomical system and principles of the various movements different from those laid down by Ptolemy and without admitting either excentrics or epicycles, and with this system all the motions are represented without error." Ibn Tofeil was therefore probably the real author of the fairly elaborate system, which his pupil worked out and handed down to us in a work on the planets, which was translated into Hebrew in the following century and from that again into Latin, and published in 1531 ³.

The object of this system was to explain the constitution of the universe as it really is, and not merely to represent the motions of the planets geometrically, so as to be able to foretell their places in the heavens at any time; and the author (be he Ibn Tofeil or Al Betrugi alias Alpetragius) specially disclaims any intention of testing the theory by comparing it with observations

(Continued from previous page)

Aristotle says is true, there is neither epicycle nor excentric, and everything turns round the centre of the Earth.

2. Munk; *Melanges de philosophie juive et arabe*. Paris, 1859, p. 412.
3. *Alpetragii Arabi Planetarum theorica phisicis rationibus probata, nuperrime latinis litteris mandata a Calo Calonymos, Hebræo Neapolitano*, Venice 1531, 28 ff. folio (published with Sacrobosco's *Sphaera*). A translation by the famous Micheal Scot has never been printed, but is still extant in Paris (Munk, *Melanges*, p. 519). The principle of the system is described by Isaac Israeli, who, however, does not mention the author's name (*Liber Jesod Olam*, II. 9, Part I, p. XI).

or of accounting for minor details of the motions.¹ The leading idea is that of the homocentric spheres, each star being attached to a sphere, and the motive power is the ninth sphere, the sphere outside that of the fixed stars. The Spanish philosopher ought, therefore, to have been content with the system of Eudoxus or its modification by Aristotle (whom he never mentions by name, but only as "the sage"), but unfortunately he became possessed with the notion that the prime mover must everywhere produce only a motion from east to west, and he had, therefore, to reject the independent motion of the planets from west to east, and revert to the old Ionian idea that the seven planets merely perform the daily revolution with a speed slightly slower than that of the fixed stars. The true speed of the *primum mobile* is a little faster than this; the eighth sphere performs a revolution in a slightly longer period (24 hours), and the effect of the prime mover is gradually weakened more and more, with increasing distance, until we find the sphere of the Moon, being furthest from the prime mover, taking nearly twenty-five hours to complete a revolution. This was the old primitive Ionian idea, but Al Betrugi (or his teacher) saw that this was not sufficient, as not only is the pole of the ecliptic different from that of the equator, which prevents the planets from moving in closed orbits, but the planets do not even keep at the same distance from the pole of the ecliptic but have each their motion in latitude, as well as variable velocity in longitude; and all this had yet to be accounted for. The ninth sphere has but one motion, but the eighth has two, that in longitude (precession) and another which is caused by the pole of the ecliptic describing a small circle round a mean position, thereby producing the supposed oscillation or trepidation of the equinoxes.² Similarly, the pole of each planet describes a small circle round a mean position (i. e. the pole of the ecliptic), thereby producing inequalities in longitude and motion in latitude.³ Whenever the actual orbit-pole of a planet is on the parallel of the mean pole, it is obvious that the planet will perform its daily revolution with its mean velocity, while the velocity is increased or lessened when the actual pole is respectively at its minimum or maximum distance from the pole of the heavens

1. Fol. 8 b.

2. Fol. 9 b.

3. Fol. 14 b. sq.

(the motion of the pole of the orbit being added to or subtracted from the motion of the planet), so that the epicycle is hereby rendered superfluous. The lengths of the radii of these small circles are not given, except in the case of Saturn, where the radius is $3^{\circ} 3'$,¹ while the mean pole of the moon is 5° (the inclination of the lunar orbit) distant from the pole of the ecliptic,² and the small circle is so exceedingly small as to produce no retrograde motion, which is also the case with the Sun. The periods of the poles of the outer planets are given by the following figures Saturn makes 57 revolutions in 59 years and $1\frac{1}{2} + \frac{1}{2}$ days, in which period the mean pole lags behind 2 revolutions $1\frac{2}{3}^{\circ} + \frac{2}{3}^{\circ}$. Jupiter makes 65 revolutions in 71 years, the mean pole lagging behind 6 revolutions. Mars makes 37 revolutions in 79 years and $3\frac{1}{2} + \frac{1}{2}$ days, the pole lagging behind 42 revolutions and $3\frac{1}{2}^{\circ}$.

In other words, the motion on these small circles are completed in the synodic periods of planets. Similarly, the pole of Venus makes 5 revolutions in the 8 years less $2\frac{1}{4}d + \frac{1}{2}^{\circ}$, lagging $1\frac{1}{2}$ revolutions in one year; and Mercury 145 revolutions in 46 years and $1\frac{1}{3}d$.⁴ It is curious that Alpetragius alters the order of the planets, placing Venus between Mars and the Sun, because the defectus (lagging) of Venus smaller than that of the Sun.⁵ He also says that nobody has given any valid reason for accepting the usually assumed order of the planets, and that Ptolemy is wrong in stating that Mercury and Venus are never exactly in a line with the Sun (a remark already made by Geber); and as they shine by their own light they would not appear as dark spots, if passing between us and the Sun. That they do not receive their light from the Sun is proved, he thinks, by the fact that they never appear crescent-shaped.⁶

There is no need to dwell any longer on this quaint theory

of spiral motion, as it has been rather improperly called.¹ It represented a retrograde step of exceedingly great magnitude, totally unjustified as the theory could not seriously pretend to be superior to the Ptolemaic system, which had only become so very simple if one was content with representing only the principal phenomena. We are told by the Jewish astronomer Isaac Israeli of Toledo, that the new system made a great sensation, but that it was not sufficiently worked out to be taken seriously, and that the system of Ptolemy, founded on the most rigorous calculations, could not be superseded by it.² Another Jewish author, Levi ben Gerson, in a work written in 1328, entered into a lengthy refutation of the hypotheses of Al Betrugi.³ But the latter certainly represented a general desire on the part of the Spanish Aristoteleans to overcome the physical difficulties in accepting the Ptolemaic system; thus Averroes says that the astronomy of Ptolemy is merely a convenient means of computing, and that he himself in his youth had hoped to prepare a work on the subject.

Nasir ed-din Al Tūsi

While ineffectual attempts were being made in the far west, to devise a new astronomical theory, the astronomers of the east did not remain blind to the desirability of finding a system, in which the planets were not supposed to move unsupported in space in such a wonderfully complicated manner; and in the thirteenth century we find one of the greatest astronomers, Nasir ed-din Al Tūsi, advocating a system of spheres which he supposed to be more acceptable than excentrics and epicycles.⁴ In addition to a review or digest of the *Syntaxis* of Ptolemy he wrote a shorter work entitled *Memorial of Astronomy*, in various

-
1. e.g. by Riccioli, *Almag. Nov.* T. I. p. 504, where Kepler's figure of the real motion of Mars in space from 1580 to 1596 (supposing the earth to be at rest) is copied, as if that had anything to do with the "Spirals" of Alpetragius.
 2. He adds that he was not qualified himself to sit in judgment on the proposed system (*Liber Jesod Olam*, II. 9, p. XI.)
 3. Munk, *Melanges* pp. 500 and 521.
 4. "*Less spheres célestes selon Nasir-Eddin Al tūsi. Par M. Carra de Vaux.*" Appendix VI. to Tannery's *Recherches sur l'astr. anc.* pp. 337—360. Includes a translation of the chapter in which the new theory is set forth.

passages of which he shows his dissatisfaction with the Ptolemaic system. In the chapter on the Moon (to which we have already alluded) he counts up the various anomalies, among which he mentions the anomaly of illumination, that is, the spots on the Moon, which he believes to be caused by other bodies moving in the lunar epicycle and unequally exposed to the Moon's light. He then says that we should expect in a simple theory to find the centre of the epicycle in equal times describing equal arcs on the deferent, and the diameter of the epicycle joining the pericentre and the apocentre pointing to the centre of the deferent. But neither of these conditions is fulfilled. In the theories of the planets he makes the same objections, which it must be said are very just, since the introduction of the equant was a very unnatural arrangement. But this is nothing to the artificial machinery designed by Ptolemy to account for the motion in latitude of the five planets, especially of Mercury and Venus. Nasir ed-din describes the marvellously complicated movements of the deferents and epicycles of these planets, and remarks that "these motions require the introduction of a system of guiding spheres, about which the ancients have not said anything". He next proceeds in the following chapter to explain a system of his own which allows us to discard these combinations.

First he proves that if there are two circles in one plane, one touching the other internally and of a diameter equal to half that of the other, and if the greater one rotates, and a point moves along the circumference of the smaller one in the opposite direction with twice the velocity and starting from the point of contact, then that point will move along a diameter of the greater circle.¹ These two circles may now be assumed to be the equators of two spheres, and for the point we may substitute a sphere representing the Moon's epicycle (1 in the figure), Nasir ed-din assumes another sphere (2) surrounding the epicycle and destined to keep the diameter from apogee to perigee in its place always coinciding with the diameter of the sphere (4) "let us give it a suitable thickness, but not too great, so as not to take up too much space." He next assumes two more spheres, one (3) which corresponds to the smaller sphere in the distance of the centre of the deferent in the Ptolemaic system from the

1. Compare Copernicus, *De revolutionibus*, III. 4 (Secular ed. 1873, p. 166).

centre of the Earth; and another sphere (4) with a diameter twice as great. Finally (4) is placed in the interior of a carrying sphere (5) concentric with the world and occupying the concavity of the

Fig. 3.—Movements of deferents and epicycles of planets.

The thickline is not a circle. All others are circles.

sphere (6), the equator of which is in the plane of the lunar orbit. (2) and (4) and (5) revolve in the same period, that in which the centre of the epicycle performs a revolution; (3) revolves in half that time, while (6) revolves in the opposite direction with the same speed as the apogee of the excentric. The figure now shows how the epicycle moves to and fro along the diameter of (4) and during the revolution of the circle (5) describes a closed curve, about which Nasir ed-din justly says that it is somewhat like a circle but is not really one, for which reason it is not a perfect substitute for the eccentric circle of Ptolemy. He estimates the greatest difference between the lunar places given by the two theories as one-sixth of a degree, half-way between syzygy and quadrature. Except for the action of the guiding sphere (2), it would not be the centre of the epicycle but the point of contact of circles (3) and (4), which describes the curve resembling a circle. The same

method may be adopted for Venus and the three outer planets, and Nasir ed-din promises to explain the new theory of Mercury in an appendix, but this appears to have been lost.

Nasir ed-din also endeavours to improve on the machinery proposed by Ptolemy to illustrate the manner in which the epicycle remains parallel to the plane of the ecliptic. He mentions that the celebrated Ibn al Haitham (afterwards known in the west as Alhazen, author of a well-known book on optics) had written a chapter on this subject, adding to each epicycle two spheres to account for the inclination of the diameter perigee-apogee, and two additional ones for the inferior planets for the diameter at right angles thereto.¹ Nasir ed-din makes use of the same principle which guided him in his demonstration about the motion in longitude, and he shows how in this way we may by means of two spheres make the extremities of the diameter of the epicycle move backwards and forwards along an arc of a sphere.² He claims that this arrangement is superior to that of Ptolemy by not introducing any error in longitude,³ but he acknowledges that he has not been able to get rid of the strong objection to Ptolemy's auxiliary circle, viz. that the irregular motion in longitude with regard to the centre of the deferent necessitates the introduction of a corresponding irregularity in the motion on the auxiliary circle by letting the motion be uniform with regard to an equant. It baffled Nasir ed-din's ingenuity to find an arrangement of spheres which could obviate the necessity of having recourse to this expedient.

All the attempts at rebellion against the Ptolemaic system had thus turned out failures. And they deserved nothing else, since it was impossible to find anything better than what Ptolemy had produced, until it was perceived that where Ptolemy was wrong was not in his mathematical methods, which were perfect, but in the fundamental idea of the Earth being at rest. The time

-
1. Ibn al Haitham said that by using discs instead of spheres one might complete the demonstration; but Nasir ed-din objects to the arrangement (about which he gives no details) that a non-spherical system is not in accordance with the principles of astronomy.
 2. It is not quite clear whether this plan is his own or is the same as Ibn al Haitham's.
 3. Due to disturbance of the position of the diameter from perigee to apogee, from which the anomaly is counted.

was apparently not ripe for a radical change with regard to this idea. Though the doctrine of the Earth's motion does not seem to have been mentioned by Arabian writers, we have evidence that the hypothesis of the daily rotation of the Earth was not unknown among them, a natural consequence of their familiarity with the writers of antiquity. One of Nasir ed-din's fellow-workers at the Meragha observatory, Ali Negm ed-din al Katibi, who died in 1277, wrote a book, the *Hikmat al-ain*, on philosophy, in which he combats this opinion, which he attributes to "some philosophers." "I do not," he says, "advance as an argument against it that, if this were the case, a bird flying in the direction of the motion of the Earth would not be able to keep up with it, because the motion of the Earth would be much faster than that of a bird, inasmuch as it returns to its place in a day and a night. Such an argument is not conclusive, because it may be urged that the atmosphere which is close to the Earth partakes of its motion as the ether partakes of the motion of the heavenly sphere. But I reject this theory, because all terrestrial motions take place in a straight line, and therefore we cannot admit that the Earth should move in a circle."¹

What reformation of astronomy could be hoped for, as long as this kind of argument could be used? We cannot see from this remark of Katibi's whether there really were any Arabian philosophers who believed in the rotation of the Earth. It is, however, stated in the *Zohar*, the great Kabbalistic work attributed to Mosheh ben Shemtob of Leon (died 1305), that a certain Rabbi Hamnuna the Elder (otherwise unknown) taught that "the Earth turns like a sphere in a circle and that some people are above and others below."² Though this passage as well as others in the *Zohar* may have been interpolated much later, it would

1. A. Sprenger, "The Copernican System of Astronomy among the Arabs," *Journ. Asiatic Society of Bengal*, Vol. XXV. (1857), p. 189. Katibi's contemporary, Abu 'l Faraj (II. p. 10) deems it necessary to prove that the Earth cannot be in motion, neither rectilinear nor circular, but his arguments (about birds and stones flung upwards) seem merely taken from Ptolemy, lib. I. cap. 6. Kazwini (*Kosmographie*, p. 296) says that among the ancients there were some adherents of Pythagoras who maintained that the Earth continually moves round in a circle; but whether these adherents were Greeks or Arabians cannot be seen from the context.
2. *Sohar*, Amsterdam, 1718, T. III. f. 10a; Gunther, *Studien Z. Gesch. d. math. Geogr.*, p. 113.

after all not be very surprising if some learned Jews had been influenced by the opinion of Herakleides, since it is an established fact that the doctrines of the Kabbalists were intimately connected with the later Greek philosophy. But any how nothing came of this isolated case, and the daily rotation of the heavens continued to be universally accepted as a self-evident fact.

Arabian astronomers and Ptolemaic system—

Arabian astronomers who really wished to follow in detail the celestial motion were therefore obliged to adopt the Ptolemaic system altogether. New planetary tables had long been found to be a necessity, and this important work was at last undertaken by King Alfonso X. of Castille and several Jewish and Christian astronomers working under him at Toledo, who prepared the celebrated Alfonsine Tables, Apparently the King must have had his doubts about the physical truth of the system, judging from his well-known saying that if God had consulted him when creating the world, he would have given Him good advice. The tables were prepared under the direction of the Jew Ishak ben Said, called Hasan, and a physician, Jehuda ben Mose Cohen, and were finished in 1252, the year in which Alfonso ascended the throne of Castille. They continued in great repute for three hundred years as the best planetary tables; they were first printed in 1483, but had been spread all over Europe long before that time in numerous MS copies, many of which are still in existence, Twenty-six codices are counted up in the *Libros del Saber de Astronomia del Rey D. Alfonso X. de Castella*, Madrid, 1863-67 (5 vols. fol.). This compilation, a series of chapters on spherical and theoretical astronomy followed by tables, must have been made up from several codices, as there are numerous repetitions even of very elementary matters. In the third volume the theories of the planets are dealt with, but one looks in vain for any improvement on Ptolemy; on the contrary, the low state of astronomy in the Middle Ages is nowhere better illustrated. In general the elements of the orbits are those of Ptolemy, though sometimes only approximations are given, while different values are given in different chapters, though Ptolemy places the centre of the deferent midway between the centre of the equant and the Earth, the *Libros del Saber* places the centre of the equant (*cerco del alaux*.¹) midway between the Earth and the centre of the deferent

1. *al* is the Arabic article, *aux* (apside) is a corruption of the Arabic *Oudj* (Abu'l Faraj, II. p. 25). The equant is called the *cerco del Y guador*.

(*cerco del levador*¹), as in Ptolemy's theory of Mercury, which the authors would seem to have extended to the planets, omitting the motion of the centre of the deferent on a small circle; this, they have, however, correctly given in the case of Mercury.² There is a very curious figure³ of the deferent of Mercury in the form of an ellipse (the axes being as 6 to 5 nearly), with what looks like the Sun in the centre. This curve has been constructed from a number of small circular arcs,⁴ and it is obviously nothing but the curve described by the centre of the epicycle of Mercury in Ptolemy's theory. For according to the latter the centre of the deferent describes a small circle with radius = $\frac{1}{31}$ of that of the deferent, in direction from east to west, in the same time which the centre of the epicycle takes to pass round the circumference of the deferent from west to east. This makes the centre of the epicycle describe a closed curve resembling an ellipse, the axes of which are in the ratio 11: 10, almost exactly the same as in the Spanish diagram, and there is therefore in the latter no anticipation whatever of Kepler's great discovery, since in the case of the inferior planets it is the epicycle which is the real orbit.⁵ The small sun-like object in the centre of the ellipse represents the centre of Ptolemy's small circle, and it has either been inserted in the manuscript centuries after the essay had been written, or, more likely, it has been caused by a small blot on the place in the parchment where the stationary leg of the draughtsman's compasses had made a small hole. An oval deferent of Mercury occurs in several books published in the sixteenth and seventeenth centuries.⁶

1. Vol. III, pp. 246—253.

2. Vol. III, pp. 253 and 278. In the latter place the radius of the small circle is $\frac{1}{31}$, as in the "*Hypotheses*" of Ptolemy.

3. Vol. III, p. 282.

4. See the lengthy description on pp. 278—280.

5. The editor, Don Manuel Rice y Sinobas, on p. xxxiii, of his preface, even goes so far as to suggest that Kepler may have known of this great discovery of Alfonso's or rather of Arzachel's, as the text attributes the construction to him. This and other similar diagrams were intended to be used instead of planetary tables in the manner afterwards adopted by Apianus.

6. First (about 1460) in Purbach's *Theoricae novae Planetarum* (ed. of Basle, 1573, p. 82): "Ex dictis apparer manifeste, centrum epicycle Mercurij,

Though the somewhat confused collection of essays entitled the *Libros del Saber* would not, if published in the thirteenth century, have advanced astronomical science, it cannot be denied that the Alfonsine Tables were very useful in their day. The actual elements are not given, nor is any thing said about any observations by which somewhat more correct values of the mean motions must have been found.¹

Arabs on motions of fixed stars.

Thus we finish our review of the planetary theories of the Arabs. Now we shall say a few words about their ideas as to the nature and motion of the fixed stars. The exaggerated notion which prevailed before the invention of the telescope with regard to the apparent angular diameters of the stars naturally, led to erroneous estimates of their actual size, founded on the assumption that the sphere of the fixed stars (the eighth sphere) was immediately outside that of Saturn.² The stars of the first magnitude were supposed to have an apparent diameter equal to $\frac{1}{2}$ of that of the Sun, from which it followed that their actual diameters were about $4\frac{3}{4}$ times that of the Earth, or about

(Continued from previous page)

propter motus supradictos non (ut in alijs planetis fit) circumferentiam deferentis circulare, sed potius figuræ, habentis similitudinem cum plana ovali peripheriam describere." Next by Albert of Brudzew in 1482 in his *Commentariolum super theoricis novas*, printed at Milan in 1495 (ed. Cracow, 1900, p. 124), where it is remarked that the centre of the lunar epicycle describes a similar figure. This is also stated by E. Reinhold in his commentary to Purbach, 1542, fol. p. 7 verso (ed. of Paris, 1558, fol. 78,) by Vurstisius in his *Questiones novae in theoricis*, & c., Basle, 1573, p. 233; and in Riccioli's *Almagestum novum* T. I. p. 564. The last three writers (who give a figure) also take the equable angular motion round the centre of the equant into account, which centre lies on the point of the circumference of the small circle nearest the Earth. The curve described by the centre of the epicycle thus becomes egg-shaped, and not like an ellipse.

1. The tables in vol. v. of the *Libros del Saber* are quite different from the Alfonsine Tables, and are apparently only intended for astrological purposes.
2. Al Battani (cap. 50) gives the greatest distance of Saturn=18,094, and the distance of the fixed stars=19,000 semidiameters of the Earth. Al Fargani (p. 82) puts them exactly equal. Al Kusgi gives the diameters in parasangs, of the concavity of the stellar sphere=33,509,180 of the ninth sphere 33,524,309, of its convexity "no one but God knows" (Shah Cholgi, p. 97).

twice that of Mars.¹ As to the nature of the stars, they seem generally to have been assumed self-luminous, being condensed parts of the sphere, though Abraham ben Chija says that the eighth sphere does not shine with a uniform light, but has denser spots, which are illuminated by the Sun and appear to us as the fixed stars.²

To account for the apparent slow motion of the stars paralleled to the ecliptic, from west to east, whereby their longitudes increase while their latitudes remain unaltered, it became necessary to introduce a ninth sphere (*primum mobile*), turning in twenty-four hours and communicating this motion to the eighth sphere, while the latter moved extremely slowly round its own axis forming an angle of $23^{\circ} 35'$ with that of the ninth.³ But the simple phenomenon of precession was by many Arabian astronomers complicated by being assumed variable. It may be mentioned that according to Theon and Proklus it had been assumed by some astronomers apparently before the time of Ptolemy, that the precessional motion of the stars was not progressive, but was confined to an oscillation along an arc of 8° , along which the equinoctial points moved backwards and forwards on the ecliptic, always at the same rate of 1° in 80 years. The absurdity of the sudden change of direction must have become obvious as soon as astronomy began to be cultivated among the Arabs, for we find that one of the earliest astronomers, Tābit ben Korra, substituted a physically less objectionable theory.⁴

1. Al Fargani (p. 85, Golius) gives the cubic contents of the six spheres as 107, 90, 72, 54, 36, 18 times that of the Earth. Abu'l Faraj, p. 199, gives a similar series from 93 to $15\frac{1}{4}$ for the average star of each class. Shems ed-din of Damascus in his *Cosmography* (p. 3) merely says that the smallest fixed star is much larger than the Earth.
2. According to Suter, p. 77, a writer called Ibn Zura wrote a treatise "On the cause of the light of the stars, though they and the spheres consist of one single substance."
3. The outermost sphere is by the philosopher Ibn Sina (Avicenna) defined as a spherical, single (not composite) body, emanating directly from God and subject to dissolution, endowed innately with circular motion as an expression of its praise of the Creator (Mehren in *Oversigt, K. Danske Vid. Selskab*, 1883, p. 70).
4. The treatise "*On the motion of the 8th sphere*" has never been printed; an abstract is given in Delambre's *Hist. de l'astr. du Moyen Age*, p. 73. Compare a quotation by Ibn Junis, Caussin, *Notices et Extraits*, VII, p. 116.

He imagines a fixed ecliptic (in the ninth sphere) which intersects the equator in two points (the mean equinoxes) under an angle of $23^{\circ} 33' 30''$, and a movable ecliptic (in the eighth sphere), attached at two diametrically opposite points to two small circles, the centres of which are in the mean equinoxes and the radii of which are $=4^{\circ} 18' 43''$. The movable tropical points of Cancer and Capricorn never leave the fixed ecliptic, but move to and fro to the extent of $8^{\circ} 37' 26''$, while two points on the movable ecliptic 90° from the tropical points move on the circumferences of the small circles, so that the movable ecliptic rises and falls on the fixed one, while the points of intersection of the equator and the movable ecliptic advance and recede to the extent of $10^{\circ} 45'$ either way. This is a motion of the eighth sphere, common to all stars, and the Sun will, therefore, sometimes reach its greatest declination in Cancer, sometimes in Gemini. Tabit does not say that the obliquity of the ecliptic is variable, and perhaps it did not occur to him that this would be a necessary consequence of his theory; he only notices the change in direction and amount of the motion of the equinoxes, which, he says, has increased since the days of Ptolemy, when it was only 1° in 100 years, while later observers have found 1° in 66 years. The erroneous value given by Ptolemy was, therefore, mainly responsible for the continuance of the imaginary theory. It is to be observed that Tabit expresses himself with a certain reservation, and seems to think that further observations are necessary to decide if the theory is true or not. His younger and greater contemporary Al Battani was even more cautious, for though he repeats the account of the trepidation given by Theon (which he says that Ptolemy *manifeste in suo libro declarat*¹) he does not make use of it, but simply adopts 1° in 66 years (or $54''.5$ a year), which he finds by a comparison between his own observations and some made by Menelaus. In rejecting the erroneous value of Ptolemy, which Al Fargani alone had accepted,² Al Battani was followed by Ibn J  nis, who came still nearer to the truth by adopting 1° in 70 years or $51''.2$ a year, and who does not allude to trepidation. It is greatly to the credit of several other Arabian writers that they were not led astray by this imaginary phe-

1. Cap. 52, (205). Plato's translation gives the period as 84 years, but Nallino's ed. has 80 (p. 127).

2. c. 13, p. 49.

3. Schj  llerup, *Descr. des   toiles fixes*, p. 43.

nomenon; among them are Al Sufi, the author of the only uranometry of the Middle Ages³, who followed Al Battani, also Abu 'l Faraj and Jagmini,¹ while Nasir ed-din mentions it but seems to doubt its reality.² By others it was willingly accepted, for instance by Al Zarkali, who made the period of oscillation of 10° either way equal to 2000 Muhammedan years (or 1940 Gregorian years, i.e. 1° in 97 years or $37''$ a year). The motion is in a circle of 10° radius; at the Hijra the movable equinox was it $40'$ in increasing precession, and in A. D. 1080 at $7^\circ 25'$.³ The diminution of the inclination of the ecliptic, which the astronomers of Al Mamun had found $=23^\circ 33'$, no doubt lent countenance to the idea of trepidation, and the next step in the development of this curious theory was the combination of progressive and oscillatory motion. Al Betrugi, who gives a sort of history of the theory, beginning with a mythical H mes, makes out that Theon (or Taun Alexandrinus as he calls him) combined the motion of 1° in 100 years with the oscillation³. A century later this was actually done, and the theory received its last development by King Alfonso or his astronomers, who⁴ perceived that the equinoxes had receded much further than Tabit's theory allowed. The equinoxes were now supposed to pass right round the heavens in 49,000 years (annual motion $=26''.45$), while the period of the inequality of trepidation was 7000 years, so that in a sort of Great Jubilee year everything was again as it had been in the beginning.⁵ The progressive motion belongs to

1. Abu 'l Faraj, p. 12, simply says that the motion is 1° in 100 years according to Ptolemy, or 1° in 66 years according to others. But on p. 18 he says that if the ancient Chaldeans gave the tropical points a motion backwards and forwards, and if ancient astrologers adopted this, then the motion of the fixed stars must have been unknown to them. Jagmini (p. 229) says that most people adopt 1° in 66 solar years.
2. *Spheres celestes*, p. 347.
3. Sedillot, *Memoire sur les instr. astr. des Arabes*, pp. 31, 32. Abraham ben Chijsa (p. 196 of Munster's *Sphaera mundi*. Basle, 1546) gives the period as 1600 years without quoting any authority. He adds that the ancient Indians, Egyptians, Chaldeans, Greeks, and Latins first proposed the theory—Ptolemy neither approved nor disapproved of it, but Al Battani confuted it.
4. Alpetragius, f. 12a. He says that Al Zarkali did the same.
5. A later writer, Augustinus Ricius, *De motu octave sphaere*, Paris, 1521, who traces the theory back to Hermes, 1985 years before Ptolemy (!) credits

(Continued on next page)

the ninth sphere; the annual precession varies between $26''.45 \pm 28''.96$, or from $+ 55''.41$ to $-2''.51$.¹ It was now necessary to assume the existence of a tenth sphere, which as *primum mobile* communicated the daily rotation to all the others, while the ninth produced the progressive and the eighth periodical motion on the small circles, which are situated "in the concavity of the ninth sphere." This was a nice and comfortable theory on account of the long periods involved and the slow changes it produced in the amount of annual precession; and oblivious of the fact that the theory had no foundation except the circumstance that the obliquity of the ecliptic was now about $20'$ less than it had been stated to be by Ptolemy, and that he had given the amount of precession as $36''$ a year instead of about $50''$, and often shutting their eyes to several of the necessary consequences of it, such as the changes in the latitudes of stars which it ought to produce², astronomers continued to accept the theory until at last a real observer of the stars arose and wiped it out by showing that the obliquity of the ecliptic had steadily diminished, and that the amount of annual precession had never varied. We have in this place only alluded to it because it involved some rearrangement of the spheres and because it is eminently characteristic of the period during which no persistent observations were taken, and hardly an attempt was made to improve the theories of Ptolemy. The theory of *trepidatio* or *titubatio*, as it was sometimes called, was one attempt and it would have been better left alone. But it forms a not uninteresting chapter in the history of astronomy.

(Continued from previous page)

this development to a Jew of Toledo, Isaac Hassan (see above. p. 38), adding that Alfonso four years after the completion of the tables became convinced of the futility of the theory by reading the book on the fixed stars by Al Sufi. Riccioli, *Almag. novum*, I. p. 166.

1. In the Alfonsine Tables the maximum took place at the birth of Christ. In Essler's *Speculum astrologicum*, p. 224 (appended to Purbach's *Theoricae novae*, Basle, 1573) the epoch is A.D. 15, diebus 137 completis. Reinhold in his commentary to Purbach (Paris, 1558, f. 163b) explains that $26''.45$ is the space passed over by the Sun in 10 mins. 44 secs., by which amount the Alfonsine Tables made the tropical year smaller than $365\frac{1}{4}$ days.
2. Abraham ben Chija (p. 103, *Schrackenfuhs*) says that trepidation does not change the latitudes. Perhaps he refers to the earliest form of the notion, that described by Theon of Alexandria.

Here we finish our review of ancient astronomy. We have omitted as not coming within our province several valuable contributions to science which did not deal with cosmology or planetary theory. But even with this limitation enough has been said to show that when Europeans again began to occupy themselves with science they found astronomy practically in the same state in which Ptolemy had left it in the second century. But the Arabs had put a powerful tool into their hands by altering the calculus of chords of Ptolemy into the calculus of sines or trigonometry, and hereby they influenced the advancement of astronomy in a most important manner.

CHAPTER II

Personal References of Brahmagupta

Sudhākara Dvivedi in his *Gaṇaka Tarāṅgiṇī*, a small book on biographical sketches of astronomers and astrologers of this country gives a brief account of Brahmagupta thus :

Brahmagupta was born in 520 Śaka (655 Vikramī or 589 A.D.) in the reign of King Vyāghramukha, belonging to the *Cāpa* family ; his father was Jīṣṇugupta ; and at the age of 30, he wrote in 550 Śaka (628 A. D.) his well known treatise on Astronomy known as the *Brāhmasphuṭasiddhānta*, which is corroborated by the statement in the *Viṣṇudharmottara Purāṇa*, (Chapter on the *Brahma-siddhānta*). His other treatise, entitled the *Khanda-Khadyaka*, which is a *karāṇa* book, was completed in 587 Śaka (665 A. D.). According to some authorities, Brahmagupta was the grandson of Jīṣṇugupta, and the family suffix (*Gupta*) indicated that he belonged to the Vaiśya family, and he was in the service of the King of Rewah, known as Vyāghrabhaṭa.

Brahmagupta was a great critic ; he did not spare any of his predecessors like Āryabhata, Varāhamihira, Śrīṣeṇa, Viṣṇucandra and others. Later on, his influence on the writing of the succeeding generations has been immense. Bhāskarācārya II in his *Bījagaṇita* has acknowledged him as a great authority on algebra and has given him as the first place amongst the galaxy consisting of Brahmagupta, Śrīdhara, Padmanābha etc. The Eighteenth Chapter of the *Brāhmasphuṭasiddhānta*, known as Kuṭṭaka Chapter (on Pulveriser) has been translated by H. T. Colebrooke in English in 1817. The English translation of the Twelfth Chapter on Gaṇita or Calculations from the *Brāhmasphuṭasiddhānta* is also available in English. (See Colebrook's *Algebra with Arithmetic and Mensuration from the Sanskrit of Brahmagupta and Bhāskara*, London, 1817).

The *Vāsanā Commentary* on the *Brāhmasphuṭasiddhānta* by Pṛthudakavāmi (660 A. D.) is also available though with difficulty (as indicated by Sudhākara Dvivedi) ; its incorrect manus-

cript is available in the Library of the King of Banaras (Kāśirā'a) which has the colophony at the end as :

श्री चापवंशतिलके श्री व्याघ्रमुखे नृपे राकनृपालात् ,
पञ्चाशत्संयुक्तैर्वर्षशतैः पञ्चभिरतीतैः ।
ब्राह्मस्फुटसिद्धान्तः सज्जनगणितहगोलवित्प्रीत्यै,
त्रिंशद्दशैः कृतो जिष्णुसुतब्रह्मगुप्तेन ॥

Bhāskara II has written the famous treatise *Siddhāntasiromani* (1150), which is almost based on the *Brahmasphuṭasiddhānta*. It has been edited by the author's own gloss (*Vāsanabhāṣya*) by Bāpu Deva Śāstrī (Vārāṇasi); by Murlidhar Jha with the commentaries, *Vāsanāvarttika* of Nṛsimha (1621) and Marici of Muniśvara (1635), vol. I (containing chapter 1 of the *Gaṇitadhyāya*) (Vārāṇasi, 1917); by Girija Prasad Dvivedi with original commentaries in Sanskrit and Hindi, vols. I and II (Lucknow, 1911, 1926); English translation of the text only by Bāpu Deva Śāstrī and Wilkinson (Calcutta, 1861).

In the very first Chapter (verse 2), Brahmagupta writes : The old calculations dealing with planets (i.e. the old astronomy), based on the system of Brahmā have become erroneous in course of past ages and therefore, I, the son of Jiṣṇugupta would like to clarify them.

Brahmagupta was not a mere theorist, he based his calculations on direct observations with the help of instruments or devices (*nalikādi yantra*); he was in favour of making corrections on the basis of these observations. He was himself an expert *observer*. In his *Khaṇḍakhadyaka* also he has emphasised the need of direct observation.

At many places, Brahmagupta has severely criticised the Romaka and Pauliśa systems of astronomy which were introduced in this country by Lāṭadeva and Śriṣeṇa. There are many passages where this criticism would be available with vehemance.

Brahmagupta was opposed to the system of Āryabhaṭa I. He never spares the school of Āryabhaṭa which was regarded as the most authoritative then. Sudhākara Dvivedi says that as Brahmagupta was opposed to the system of Āryabhaṭa, so the *Vaṭeśvara Siddhānta* was opposed to that of Brahmagupta. The Institute has already published the *Vaṭeśvara Siddhānta* and now it has the privilege of publishing the *Brahmasphuṭasiddhānta*.

A Note on Bhillamāla

It is said that Brahmagupta completed his *Brāhmasphuṭa-siddhānta* in Śaka 550, and he has come to be known as Bhillamālakācārya or a teacher residing in "Bhillamālaka." In this connection, therefore, it would be interesting to reproduce a note on *Bhillamāla* from G. Bühler's article on *Gurjara Inscriptions*, No. III, published in the *Indian Antiquary*, July 1888, vol. 17, p. 192 :

With a single exception all the complete inscriptions call the princes enumerated above, scions of the Gurjara race; and *Khe* I. and II. highly extol the greatness and wide extent of this family. *Na.* alone names the Mahārāja Karna as their ancestor. With respect to this personage it is for the present impossible to say whether the famous hero of the *Mahābhārata* may be meant, or some real historical king. But the name *Gurjara* makes it evident that this dynasty belonged to the great tribe which is still found in Northern and Western India and after which two provinces, one in the Bombay Presidency and one in the Pañjāba, have been named. The Gurjaras or *Gūjars* are at present pretty numerous in the western Himālaya, in the Pañjāba and in Eastern Rājputānā. In Kachh and Gujarāt their number is much smaller. It would, therefore, seem that they came into Western India from the north. Their immigration must have taken place in early times, about the beginning of our era or shortly afterwards. In Western India they founded, besides the kingdom of Broach, another larger state which lay some hundred miles further north. Hiuen Tsiang mentions in his travels¹ the kingdom of *Kiu-che-lo* and its capital *Pi-lo-mi-lo*. It has been long known that the former word corresponds to Gurjara.

But the name of the town has been incorrectly connected by the French scholars with Bālmer in the Jēsalmīr territory, and this identification has been accepted in Mr. Beal's new translation of *Siyuki*. As I have stated already formerly² following Colonel. J. Watson, *Pilomilo* corresponds exactly to Bhillamāla

1. Beal, *Siyuki*, Vol. II, p. 269f. Hiuen Tsiang assigns to the northern Gurjara State an extent about double of that given for the kingdom of Broach.

2. *Ante*, Vol. VI, P. 63.

one of the old names of the modern Bhīnmāl or Śrīmāl' in southern Mārvād close to the northern frontier of Guṛarāt. Another work, which was composed a few years before Hiuen Tsiang's visit to Guṛarāt, contains likewise a notice of this northern kingdom of the Gurjaras. The astronomer, Brahmagupta, who completed his *Siddhānta* in Śaka-Samvat 550 or 628 A.D. calls himself Bhīllamālakakācārya², "the teacher residing in Bhīllamāla and is called so by his commentator Prthūdakaśvāmin. He further states that he wrote under king Vyāghramukha who was 'an ornament of the Cāpa race.' This family, whose name recurs in the Haḍḍāla grant of Dharaṇivarāha³ prince of Vadhvān, thus seems to have been the reigning house of Bhīllamāla. It is most probably identical with the Caudas, Cāvōtakas⁴ or Chāpōtkatas, who from 756 to 941 A.D. held Anhilvād and still possess various small districts in northern Guṛarāt. The Gurjara kingdom of Broach was without a doubt an offshoot of the larger State in the north, and it may be that its rulers, too, belonged to the Cāpa family.

1. Bhīllamāla means etymologically 'the field of the Bhil' and Śrīmāla 'the field of Sri'. The latter name must also be ancient, as the Śrīmālī Brāhmaṇas are called after it. The Jainas narrate various, of course incredible, legends, which explain how Śrīmāla came to be called Bhīllamāla. Merutunga says that king Rhoja invented the latter name, because the people of Śrīmāla let the poet Māgha die of starvation. According to another authority, the town had a different name in each Yuga. It is in India very common for ancient towns to have two or even more names. Thus Kanauj was called, Kānyakubja, Gādhīpura, and Mahodaya.

2. See Professor A. Weber, *Die Sanskrit und Prakrit Handschriften der Berliner Bibliothek* Vol. II. pp. 297-298. In the first passage the MSS. offers incorrectly Bhīlamācārya; in the second which occurs in the commentary on the *Khaṇḍakhādyaka*, we have Bhīllamālavakācārya, a slightly corrupt reading. This latter varia lectio occurs also in other MSS., see Weber, *Indische Streifen*. Vol. III, p. 90, and has given rise to erroneous suppositions regarding Brahmagupta's home. The Gujarāṭi Joshis still preserve the tradition that Brahmagupta was a native of Bhīnmāla.

3. Ante, Vol. XII. p. 190ff. The remark which I have made there that the Cāpas are not named elsewhere, of course requires correction.

4. The form Cāvōtaka, which occurs in Dr. Bhagavanlal's grant of the Gujarāt Cālukya king Pulakeśin of Samvat 490, is the immediate predecessor of the word Caudas. Its Sanskrit original is certainly not cāpōtkata which probably has been coined in comparatively speaking modern times, in order to explain the difficult Prakrit word, just as the bards of Rajputana have invented Rāstraudha as etymon for Rāthōḍ.

Brahmagupta's own References

In the Twenty-fourth Chapter (*Saṅjñādhyaṃya*), of the *Brāhmasphuṭasiddhānta*, Brahmagupta has made a reference to his own biography: In the reign of Vyāghramukha belonging to the family of Cāpa, in the year 550 Śaka the treatise *Brāhmasphuṭasiddhānta* was composed for the benefit of benevolent astronomers by Brahmagupta, son of Jīṣṇugupta at the age of 30. (*BrSpSi*. XXIV. 7. 8)

Then again he says: The *Brāhmasphuṭasiddhānta* has been written by Brahmagupta, son of Jīṣṇu, in 1008 verses of Āryāchanda. (*ibid* 10)

In the beginning of this *Saṅjñādhyaṃya*, he refers to the differences in fundamental notions created by the various existing systems of astronomy as the *Sūrya-siddhānta*, *Pulisa-siddhānta*, *Romaka-siddhānta*, *Vasiṣṭha-siddhānta* and other *Yavana-siddhāntas*, which have caused anomalies in the calculations of eclipses. He also refers to the anomalies due to the calculations based on midnight day-reckoning and sunrise day-reckoning.

From the point of view of own references, the following would be of interest:

Brahmagupta, son of Jīṣṇugupta (Jīṣṇusuta-Brahmagupta):
BrSpSi. I. 2; XVI. 35. 37; XXIV. 8. 10; XXV. 73.

It is strange that in the *Khaṇḍakhāḍyaka*, Brahmagupta has not given his name nor his father's name anywhere. At least the reading of the *Khaṇḍakhāḍyaka* as given by Pṛthūdakasvāmī does not contain this name. In the edition of Bhaṭṭotpala, there are three more chapters in the *Khaṇḍakhāḍyaka* (Chapters IX, X and XI). In the Chapter XI (known as *Pātādhikāra*), we have 21 verses and in the last 21st verse we find the name of Brahmagupta,¹ son of Jīṣṇu mentioned:

Those who are eager to have the knowledge of the motion of stars and planets, for them and for the benefit of disciples in this field, Brahmagupta son of Jīṣṇu has composed this *Khaṇḍakhāḍyaka*.

1. खण्डखाद्यकमिदं तृप्त्यर्थं ग्रहगतिबुधार्त्तानाम् ।

शिष्याणां हितार्थं प्रोक्तं जिष्णुसुतब्रह्मगुप्तेन ॥

Reference to Āryabhata

We have said that it appears that Brahmagupta was a bitter opponent of Āryabhata in his younger days (623 A. D.), but later on (in 665 A. D.), he climbed down to describe and teach one of the Āryabhata's system of astronomy. Āryabhata was universally revered, and it was difficult for Brahmagupta to have ignored him and thus he has to refer to this great authority some times to oppose some of his views and some times to expound his views. The following are the passages in the *Brahmasphuṭasiddhanta*, where the author has referred to the name of Āryabhata. There are many other passages where the name "Āryabhata" does not occur but where Brahmagupta indirectly means to quote the views of this great master.

BrSpSi. I. 9. 12. 28. 32. 60. 61 ; II. 33. 46; V. 21.25; VI. 13; IX.10; XI. 4. 9. 10. 12. 25. 29. 33. 41. 42. 43. 44. 46. 47. 49. 62; XIII. 27; XIV. 45; XVI. 37. 46; XXI. 39.

The largest references are in Chapter XI, where Brahmagupta has made an attempt to show the discrepancies of the Āryabhatīya system of reckoning astronomical observations and constants.

In the *Khandakhadyaka* also there is a reference to the name of Āryabhata but on very few occasions. In Chapter I, we have this reference at three places-

Having made obeisance to God Mahādeva, who is the great cause of this world's rise (i.e. creation), existence and destruction, I shall declare the *Khandakhadyaka* (i.e. a short treatise on astronomy, which is as pleasant as food prepared with sugarcandy), which will yield the same results as the great astronomical treatise of Āryabhata. As in most cases calculation by the great work of Āryabhata, for (the knowledge of time and longitude of planets etc. at) marriage, nativity and the like, is impracticable for common use every day, this smaller treatise is made so as to yield the same results as that. ¹

1. प्रणिपत्य महादेवं जगदुत्पत्तिस्थितिप्रलयहेतुम् ।
क्त्वामि खण्डखाद्यकमाचार्य्यमट तुल्यफलम् ॥
प्रायेणार्थ्यमटेन व्यवहारः प्रतिदिनं यतोऽशक्यः ।
उदाहजतकादिषु तत्समफललघुतरोक्तिरतः ॥

These two verses show that Brahmagupta was not hostile to Āryabhāṭa when he wrote this *Khaṇḍakhādya*; he merely intends presenting the subject matter on simple lines and furnishing the results obtained by Āryabhāṭa in a simpler way.

In the following verse of the same chapter, he refers to Āryabhāṭa's midnight day-reckoning system :

The mean Saturn diminished by 3 seconds, the Śighrocca of Mercury diminished by 22 seconds, the mean Mars increased by 2 seconds and the mean Jupiter increased by 4 seconds are equal to the respective mean planets of Āryabhāṭa's "midnight-system".¹

In the Appendix of the *Khaṇḍakhādya* known as *Khaṇḍakhādya-kottara*, we again find a few verses where the name of Āryabhāṭa occurs; Three of these verses have been reproduced from the *Brāhmasphuṭasiddhānta* (*BrSpSi* I. 62, 63; II.47) :

Āryabhāṭa made the apogee of the Moon as moving more quickly and the node as moving more slowly than their actual motions ; if his constants give correct results in relation to the end of *tithis* [i. e. conjunction etc.] or eclipses, they must be considered as accidental as are the letters cut into wood by weevils. (*KK*. IX.1; *BrSpSi*. I. 62)

On seeing me, who possess the most accurate knowledge of mean motions, men who have learnt from the works of Śriṣeṇa, Viṣṇucandra and Āryabhāṭa, cannot face me in any meeting just like deer on seeing a lion (*KK*. IX. 2; *BrSpSi*. I. 63)

As the apparent planets beginning with Mars as derived from the works of Śriṣeṇa, Āryabhāṭa and Viṣṇucandra, are far deviated from their true places, the works of these authors are therefore not valued among the learned.² (*KK*. IX. 3; *BrSpSi*. II. 47)

1. तिसृभिः शनिर्ज्ञशीघ्रं द्वाविंशत्या कुजोऽधिको द्वाभ्याम् ।

चतसृभिरधिको जीवोऽर्द्धं रात्रिकार्य्यभटमव्यसमाः ॥

—*KK*. I. 7

2. अकृतार्य्यभटः शीघ्रगमिन्दूच्चं पातमल्पं स्वगतेः ।

तिथ्यन्त ग्रहणानां घुणान्नरं तस्य संवादः ॥१॥

मध्यगतित्वां वीक्ष्य श्रीषेणार्य्यभट विष्णुचन्द्रज्ञाः ।

सदसि न भवन्त्यभिमुखाः सिंहं दृष्ट्वा यथा हरिणाः ॥२॥

दूरभ्रष्टाः स्पष्टाः श्रीषेणार्य्यभटविष्णुचन्द्रेषु ।

यस्मात् कुजादयस्ते विदुषां नैवादरस्तस्मात् ॥३॥

—*KK*. IX. 1-3

In the Appendix of the *Khaṇḍakhādyaka*, there is another verse which also speaks in the same strain against Āryabhaṭa (this verse does not occur in the *Brāhmasphuṭasiddhānta*) :

As the process of finding the apparent places of planets as given by Āryabhaṭa does not make them agree with observation, I shall, therefore, speak of this process. Of the Sun the apogee is at two signs and seventeen degrees (*KK. IX. 4*)¹

Brahmagupta opposed to Śrīṣeṇa—

Viṣṇucandra, Lāṭa, Vijayanandī and others

Brahmagupta was a great critic; he did not spare Āryabhaṭa, and along with him he was vehemently opposed to the doctrine of Śrīṣeṇa, Viṣṇucandra, Lāṭadeva, Vijayanandī and Pradyumna also. He was opposed to the *Romaka* and *Paulīśa Siddhāntas*, which were the systems of foreign astronomy, derived from Greece, Babylonia and other centres of learning. He did his best to resist the foreign influences on astronomy.

The following are the verses in the *Brāhmasphuṭasiddhānta*, where Brahmagupta expressed his note of discord against the systems or notions of Āryabhaṭa, Śrīṣeṇa and Viṣṇucandra :

BrSpSi. I.60; II 46, 47; X 13, 62; XI.31, 46, 47, 48-50, 55, XVI. 36, 46; XXI.39; XXII. 2.

In two of the verses, he refers to Lāṭasimha :

BrSpSi. XI. 46, 48.

In the following verse, he refers to Anḱaciti, Vijayanandī, Pradyumna and others: *BrSpSi.* XI. 58.

In the *Khaṇḍakhādyaka* we do not find the names of these adversaries of Brahmagupta ; we, however, have a reference of Śrīṣeṇa, Āryabhaṭa and Viṣṇucandra in the verses already quoted, occurring in the Appendix of the *Khaṇḍakhādyaka* (*Khaṇḍakhādyakottara*), Chapter IX. 2 and 3. As we have said before, these verses of the Appendix have been reproduced from the *Brāhmasphuṭasiddhānta*. (I.62 and II.47).

Reference to Romaka and Paulīśa systems

Brahmagupta speaks of his system as if expounded by Brahmagupta himself for the first time, later on deteriorated, and then revived by Brahmagupta himself. The very second verse of the *Brahma-*

1. न स्फुटमार्गमोक्तं स्पष्टीकरणं यतस्ततो वक्ष्ये ।

मानुमतो मन्दोच्चं राशिद्वयमंशकारान् सप्तदश ॥

sphuṭasiddhānta (I. 2) substantiates this view :

The science of astronomy (or the calculations of heavenly bodies) in course of long duration became ineffective or erroneous; this was revived by Brahmagupta, son of Jīṣṇu.¹ (*BrSpSi*. I.2).

The system of astronomy which goes by the name Brahma (*Brahmasiddhānta*) has been handed down to us in three forms : (i) one is as treated by the *Śākalya Samhitā*, (ii) one as described in prose in the *Viṣṇudharmottara Purāṇa*, and (iii) the one described by Varāhamihira in the *Pañcasiddhāntikā*, which recognises the *yuga* of the duration of five years. Which of these three was accepted by Brahmagupta is not clear. But from the measures of the number of revolutions performed by a planet in a given period (*graha-bhagaṇa*) etc., it is clear that Brahmagupta acknowledges the system as propounded in the *Viṣṇudharmottara Purāṇa*. In his chapter "*Tantra-parikṣādhyāya* or *Dūṣanādhyāya*", he contradicts the notions of the *Vedāṅga Jyotiṣa* which accepts the *yuga* of five years.

We may further emphasize the fact that Brahmagupta has not clearly detailed out the errors to which the Brahma-siddhānta succumbed in course of time, and how these errors were eradicated by him. During the days of Brahmagupta, Romaka and Pauliśa systems were getting currency in this country. Reference to these two are found in the *Brāhmasphuṭasiddhānta* at several places as follows :

ROMAK : I.13; XI.50; XXIV.3

PAULIŚA : XIV.45; XXIV.3

In fact, *BrSpSi*. XXIV.3, we find the line "*Sūryendu-Puliśa-Romaka-Vasiṣṭha-Yavanādyaiḥ*", where we have a reference to all the then existing systems : *Sūrya-siddhānta*, *Indu-siddhānta*, *Puliśa-siddhānta*, *Vasiṣṭha-siddhānta*, and other *Yavana-siddhāntas*. Just as the Sun is one, so the astronomical system is also one; this is a different thing that calculations in different systems may vary according to different sunrises in different places.

Brahmagupta refers at one place to Varāhamihira in *BrSpSi*. XXI.39, where he has been spoken of in connection with a list of

१. ब्रह्मणोक्तं ग्रहगणितं महता कालेन यत् खिलीभूतम् ।

अभिधीयते स्फुटं तज्जिष्णुसुतब्रह्मगुप्तेन ॥

— *BrSpSi*. I. 2.

anti-authoritative versions of astronomical systems :

Evam Varāhamihira-Śriṣenācāryabhāṭa-Viṣṇucandrādyaiḥ

Lokaviruddhamabhihitam Veda-smṛtisaṃhitābāhyam.

At one place, he mentions the difference between the calculations based on the system of Āryabhāṭa and the Pañca-siddhāntas (Five systems) : Pauliśa, Romaka, Vasiṣṭha, Saura, and Paitāmaha. (*BrSpSi*. XIV.46).

Brahmagupta was also familiar with the Jaina systems of astronomy; for example, at one place he uses the term "Jinoktam" (i.e., one propounded by the Jainas) : He repudiates the concept of *two Suns and two Moons* "*Dvāvarkaindavau*" (do canda do suiḥ) (*BrSpSi*. XI.3) as enunciated by the Jainas.

At several places we find a reference to the *Vasiṣṭha-siddhānta* (*BrSpSi*. XI.49, 50; XXIV.3)

Wherever, Brahmagupta has to press for his views in preference to the views of others, he uses the words *Brahma* or *Brahmokta* : *BrSpSi*.

Brahma : I.32; X.62; XI, 61; XVI.37

Brahmokta : II.31, 33; X.63, 69; XV.59; XVI.33

CHAPTER III

Manuscripts of the Brāhmasphuṭa Siddhānta

Sudhākara Dvivedī has given an account of some of the manuscripts of the *Brāhmasphuṭasiddhānta* in his *Bhūmika* or Introduction appended to the edition published in the PANDITA, Vol. XXIV, 1902 (New Series) : (i) available in the Library of the Government College, Kashi (Varāṇasi) i. e. Kāśika-Rājakiya-Pāṭhālaya, (ii) Dr. Thibaut's Manuscript, (iii) the Manuscript in possession with Yajñadatta Sharmā, the Chief Astronomer attached to the Prince of Ayodhyā. It is further mentioned that Dr. Thibaut's Manuscript was a copy of a Manuscript available in the Deccan College, Poona. The Manuscripts (ii) and (iii) were identical. The Manuscripts (iii) was very faulty and incorrect.

The Manuscript from which Colebrooke translated out in English the Twelfth and the Eighteenth Chapters on *Gaṇita* or Mathematics and *Kuṭṭaka* (the Chapter on Pulveriser) respectively, appeared to be different from the three Manuscripts described above. The readings differed considerably. The *Kuṭṭaka* Chapter of that book is, writes Sudhākara Dvivedī, still available in the India Office Library. (See Catalogue of the Sanskrit¹ Manuscripts in the Library of India Office, Part V. p. 995).¹

1. एतत्कृतस्यास्य सिद्धान्तग्रन्थस्यैका प्रतिः काशिकराजकीय पाठालयतो द्वितीया डा० थिबौ साहिब महाशयतस्तृतीया चायोध्यानरेशप्रधानज्योतिर्विच्छेद्यहदत्तशर्मणो मया लब्धा । डा० थिबौमहाशयस्य पुस्तकं कश्चिद्दक्षिणदेशीय (Deccan College, Poona) डेका पुस्तकस्य प्रत्यन्तरम् । इदं पुस्तकं तथा पं० श्री यहदत्त पुस्तकं चैकमातृकमेव । इदं पुस्तकत्रयमतीवाशुद्धं बहु च स्वलिप्तं चास्ति ।

(Continued on next page)

Colebrooke procured a Manuscript of the *Prthūdaka Svāmī's* Annotation on the *Brāhmasphuṭasiddhānta* from somewhere in India. This is also available in the India office Library, London. Undoubtedly it appears that this Manuscript is a copy from one written in the *Maithila* script. Dvivedī describes a few characteristics of this Manuscript. For example, on the Folio 11. 7 (७) is written instead of 9 (९). At a few other places also, the same has happened. Following a *visarga*, (*kva* क्व) is inscribed instead of '*ka*' (क), for example refer to Folio 12, line 6. At some places instead of *visarga* (:) we find *ṣa* (ष) inscribed, for example on Folio 12, line 1. Sometimes we find a *sandhi* at the *virāma* or end of a sentence; e. g. in the *Golādhyāya*, Folio 21, line 2: *sarvamupapannamuktamakhaṇḍena* (सर्वमुपपन्नमुक्तमखण्डेन). At some places we find *nū* (नू) written in place of *nta* (न्त). In one of the Folios, *Śrī Gaṇeśāya namaḥ*. श्रीगणेशायनमः is written in *Maithila* script.¹ Sudhākara Dvivedī prepared a copy of this Manuscript for Dr. Thibaut, and this copy was available with Sudhākara Dvivedī when he published his commentary with Text in the *Paṇḍita*. During the course of binding, on account of carelessness, many of the Folios got misarranged, and many of them got fragmented. Sudhākara Dvivedī emphasises in his Introduction the need of careful research on the arrangement of these Folios and their readings. (See *Catalogue of the Sanskrit Manuscripts in the Library of India Office*, Part V, p. 993-995).

Sudhākara Dvivedī with considerable efforts could rearrange the Text :

Golādhyāya-Bhāṣyam 1 to 45, mutilated at the beginning
Madhyamadhikāra-Bhāṣyam 45 to 59

(Continued from previous page)

भवेने अस्य पुस्तकस्य पुटकवन्धनकालेऽनवधानतया पत्राण्यसंगतानि जातानि, बहुत्र खण्डितानि च सन्ति । तानि कदाचिदनुपयुक्तपत्राणां मध्ये स्थिरिति तेषां सम्यगन्वेषणं समुचितम् । (See *Catalogue of the Sanskrit Manuscripts in the Library of India Office* Part, V, Page 993-995)

1. इदं पुस्तक कस्यचिन्मिथिलाक्षरैर्लिखितस्य पुस्तकस्य प्रत्यन्तरमिति निःसंशयं प्रतिभाति । ११ पत्रे, ६ इत्यस्य स्थाने ७ इति लेखात् । एवमन्यत्रापि । विसर्गात् परतः 'क' स्थाने 'क्व' इति लेखात् । यथा १२ पत्रे, ६ पंक्तौ । तथा विसर्गस्थाने 'ष' इति लेखात्, यथा १२ पत्रे, १ पंक्तौ । बावय-किरामेपि सन्धिकरणात् । यथा गोलाध्यायस्य २१ पत्रे, २ पंक्तौ सर्वमुपपन्नमुक्तमखण्डेन । कुत्रचित् 'न्त' स्थाने 'नू' इति लेखात् । एकस्मिन् पत्रे मैथिलाक्षरैः श्री गणेशायनमः इति लेखाच्च ।

In this, the commentary is up to verse 31. In the *Spaṣṭādhikāra*, the commentary begins from verse 29. Folio 60. At the top of the Folio, we have the old numbering 1 and 115.

After this, 68 folios are mis-arranged, and there the old numbering is marked 9.

After that, up to 87 folio, we have in the bound volume a commentary up to the verse 6 of *Tripraśnādhikāra*. Here the old numbering is marked 28. Then we have the commentary up to verse 27 of the *Tripraśnādhikāra*. Here the numbering of folios is marked 1 and 159 (old numbering) and 218 new. After this, then we have in the bound volume, commentary up to verse 33 of the *Tripraśnādhikāra*. On the last folio, the old numbering is marked 5 and 163, the new numbering 222. After this begins the commentary on the *Candra-grahāṇādhikāra* from verse 4, old numbering 1 and 297 and new numbering 257. Then follows the commentary on *Sūryagrahaṇa* up to verse 23. The last old folio numbering is 36 and 232, the new numbering 292. This is the last folio-numbering of the volume in the India Office Library. After this, begins the commentary on *Grahayutyadhikāra*, verse 11, old numbering 1 and 164 and the new numbering 223.

Then follows the *Madhyagatyuttarādhya* up to verse 40, old folio numbering 119, and new numbering 178. Then we have the commentary of the *Madhyagatyuttarādhya* beginning from the verse 45; the old folio numbering 120 and the new numbering 179. Then we have the commentary on *Tripraśnottarādhya* up to verse 56. Here the last old folio number is 48 and 158, and the new numbering 217.

In this way, we have the commentary on : the mutilated *Golādhya*, mutilated *Madhyumādhikāra*, mutilated *Spaṣṭādhikāra*, mutilated *Tripraśnādhikāra*, mutilated *Candra-grahāṇādhikāra*, mutilated *Sūrya-grahāṇādhikāra*, mutilated *Grahayutyadhikāra*, *Bhagrahayutyadhikāra*, *Tantra-parikṣādhya* (also known as *Dūśādhikāra*), *Ganitādhya* (Arithmetic), mutilated *Madhyagatyuttarādhya*, *Sphuṭagatyuttarādhya*, mutilated *Tripraśnottarādhya*.¹

1. मया महताऽऽयासेन तत्प्रति-पाठक्रम एवं नियोजितः ।

गोलाध्यायभाष्यम् १-४५ आदौ खण्डितम् ।

मध्यमाधिकारभाष्यम् ४५-५१ ।

(Continued on next page)

Sudhākara Dvivedi says that nowhere in the *Brahma-Sphuṭasiddhānta*, *Madhyamādhikāra*, is found the verse :

*Samsādhyā spaṣṭataram bijam nalikādiyantrēna.
Tat-saṁsṛtagrahebhyaḥ kartavyau nirṇayādeṣau.*

(This verse has been quoted by Dvivedi in the *Gaṇaka-Taranginī*, page 19).¹

This verse has been quoted by Dvivedi from the Translation of *Grahalāghava* by Mallāri.

Dvivedi further says that in the Manuscripts available, there is mentioned a Twenty-fifth Chapter under the title "*Dhyānagrahopadesādhyāya*". Dvivedi thinks that this Chapter does not constitute the *Brahmasphuṭasiddhānta* proper, which ends in fact with twenty-four chapters.² In his commentary and Edition in the *Pandita*, he has published it as a separate treatise of Brahmagupta. Thus he has named his Edition as :

अत्र मध्यमाधिकारे ३१ श्लोकपर्यन्तमेव भाष्यम् ।

अतः स्पष्टाधिकारस्य २६ श्लोकतष्टीकाऽऽरब्धा ५० पत्रतोऽत्र प्राचीन संख्या पत्रोपरि १, तथा ११५ ।

अग्रेऽत्र ६८ पत्रमसंगतम्, यत्र प्राचीन संख्या ६ ।

ततः ८७ पत्रपर्यन्तं संलग्नग्रन्थस्त्रिप्रश्नाधिकारस्य ६ श्लोकपर्यन्तं टीका । अत्र प्राचीनपत्रसंख्या २८ । ततस्त्रिप्रश्नाधिकारस्य २७ श्लोकतष्टीका, पत्रसंख्या प्राचीना १ तथा १५६, नवीना २१८ । अग्रे संलग्न ग्रन्थस्य त्रिप्रश्नाधिकारस्य ३३ श्लोकपर्यन्तं टीकान्तिमपत्रप्राचीनसंख्या ५ तथा १६३, नवीना संख्या च २२२ । ततश्चन्द्रग्रहणाधिकारस्य ४ श्लोक टीकाऽर्वा प्राचीनपत्रसंख्या १ तथा २६७ । नवीना संख्या च २५७ । ततः सूर्यग्रहणस्य २३ श्लोकपर्यन्तं टीका । अन्तिम प्राचीन पत्रसंख्या ३६ तथा २३२, नवीना संख्या च २६२ । इण्डिया-आफिस पुस्तकपुटके चैयमन्तिमपत्रसंख्या । ततो ग्रहयुत्यधिकारस्य ११ श्लोकतष्टीकाऽर्वा यत्र प्राचीनपत्रसंख्या १ तथा १६४, नवीना संख्या २२३ । ततो मध्यमगत्युत्तराध्यायस्य ।

1. सर्वेष्वपि पुस्तकेषु 'संसाध्य स्पष्टतरं बीजं नलिकादिवेत्रेण' इत्यादिश्लोको मध्यमाधिकारे नास्ति । मया गणकतरंगिण्या मल्लारिकृतग्रहलाघवटीकातो व्यलेखि (द्रष्टव्या गणकतरंगिण्यो ५०-१८१६) ।

Brahmasphuṭasiddhānto Dhyānagrahopadesādhyaśca or *Brahmasphuṭasiddhānta* and *Dhyānagrahopadesādhya* by Brahmagupta (1902)¹

The manuscript of this small treatise was also mutilated, and Dvivedi took special pains in editing it, and he revised the calculations also incorporated in this treatise.

The small treatise, *Dhyānagrahopadesādhya* must have been composed prior to the *Brahmasphuṭasiddhānta*, since we find a verse in the last Chapter (the 24th Chapter also known as the *Saṁjñādhya* of the *Brahmasphuṭasiddhānta*), verse 9, a reference to this book :

How could this result be obtained in a simple way has been shown by me in the *Dhyānagrahopadesādhya* of 72 Āryā verses, and therefore, it is not repeated here. *BrSpSi*. XXIV. 9)

In the *Dhyānagrahopadesādhya*, we have a verse 61, which is also found in the *Khaṇḍakhādyaka* (KK. I. 21) :

Navatithayaḥ (159) divided by *aṣṭi* (16), *pañcarasāḥ* (65) divided by *vasu* (8), 10 divided by 3, each multiplied by the equinoctial shadow are the (tabular differences of) ascensional difference expressed in *vināḍis*. (KK. I. 21; *DhGr*. 61)

This verse then indicates that the *Dhyānagrahopadesādhya* has been composed after the *Khaṇḍakhādyaka*. It may also be possible that the *Brahmasphuṭasiddhānta* and the *Dhyānagrahopadesādhya* were simultaneously written, and the above verse (*DhGr*. 61) was repeated again in the *Khaṇḍakhādyaka*.

Sudhākara Dvivedi has taken the help from the commentary of Pṛthūdaka Svāmī in the Chapters on *Paṭiganita* (Arithmetic), and has quoted the examples from this commentary. At many places he has corrected the readings which were mutilated in manuscripts.

1. उपलब्धमूलपुस्तकत्रये पञ्चविंशतितमेध्याये वस्तुतो ब्रह्मगुप्तकृतो ध्यानग्रहोपदेशाध्यायो वर्ततेऽतो मयायं पृथक्त्वेन तन्नाम्ना मुद्रितः । अत्र बहुत्र स्खलितानि पदानि तानि गणितेन संशोध्य मुद्रितान्यपि सुवीभिर्भृशं विचिन्तयानि ।

अस्य सिद्धान्तस्य चतुर्विंशतितमेऽन्तिमे संज्ञाध्याये (पृ० ४०८)

गणितेन फले सिद्धिर्ब्राह्मे ध्यानग्रहे यतोऽध्याये ।

ध्यानग्रहो द्विसप्ततिरायोणां न लिखितोऽत्र मया ॥

इति नवमश्लोकेन ध्यानग्रहोपदेशाध्यायस्य रचनेतत्सिद्धान्तरचनातः पूर्वं विभाति परन्तु तत्राहर्गणसाधनप्रकरणेण सिद्धान्तरचनाकाल एवास्य रचना सिध्यति तथा 'नवतिथयोष्टिविभक्ता' इत्यादि-गण्येन खण्डखाद्यरचनातः पश्चात् सिध्यति ।

Subject Matter Classified in the Brāhmasphuṭasiddhānta & Khaṇḍakhādya

It needs no emphasis that Āryabhaṭa commanded a great influence as an astronomer not only prior to Brahmagupta but during his days also, and we have seen how Brahmagupta quoted this great authority in his writings, sometimes borrowing from him and sometimes contradicting him or improving upon his calculations. Āryabhaṭa's great work is known as the *Āryabhaṭīyam* written in 499 A. D. Āryabhaṭa was born in 476 A. D. (Kaliyuga Saṃvat 3577). The *Āryabhaṭīyam* is also known as the *Āryasiddhānta*. For details about Āryabhaṭa the reader is referred to the Chapter entitled "Āryabhaṭa lays Foundations of Algebra" (*Founders of Sciences in Ancient India*, 1965, Chapter X). This great work was written in Kusumapura, (modern Patna, Bihar).

Divisions of Āryabhaṭīyam

The *Āryabhaṭīyam* is divided into four chapters called *Pada*: (i) the *Gitika Pada*, with ten verses; (ii) the *Gaṇita Pada* with 33 verses; (iii) the *Kalakriyā Pada* with 25 verses and (vi) the *Gola Pada* with 50 verses.

In the *Gaṇita Pada*, a chapter on mathematics, we have such subjects : squares (*varga*), cubes (*ghana*) (verse 3), square-root (*vargamūla*) (4), cube-root (*ghanamūla*) (5) ; area of a triangle, volume of a prism (6), area of a circle, volume of a sphere (7), area of a quadrilateral (*viṣamacaturāsra*) (8); circumference of a circle (10), Rsine (radius x sine) (*Jīva*) (11); determination of the Rsine of the zenith distance, the base (*bāhu*) of a right-angled triangle, and the upright (*koṭi*) of a right-angled triangle (16) ; hypotenuse (*kārṇa*) of a right-angled triangle and *ardhajyā* (17), Reversed-sine (*śara*) (18), areas of series-figures (*śreḍhīphala*) (19), rule of three (*trairāśika*) (23), reduction of fractions (*savarṇīkaraṇa* of *bhinnā*) (27) ; inverse-rule of three (*vyasta*) (28) ;

evaluation of unknown values (*mūlya-pradarśana* of *avyakta mūlya* (30); and the theory of pulveriser (*Kuṭṭaka*) (32, 33). In this chapter, Āryabhaṭa gives the solutions of quadratic equations, and thus he earns for himself the credit of founding the science of algebra.

(iii) The *Kalakriyā Pada* with 25 verses, which enumerates the units of time [1 year (*varṣa*)=12 months (*māsa*); 1 month=30 days (*divasa*); 1 day=60 *nāḍis*; 1 *nāḍi*=60 *vināḍi*; *vināḍi* or *vināḍikā* is the same as *vighaṭikā* equivalent to our 24 seconds; *nāḍi* or *nāḍikā* or *ghaṭi* is equal to 24 minutes]¹; correlation of time division with the *kṣetra*—division or angular division.² Twelve signs of Zodiac or *rāśis* go to constitute a *bhagana*³; solar day (*ravimāsa*), lunar day (*śasi māsa*); additional month or intercalary month (*adhimāsa*); various kinds of years: the solar year is human or *manuṣya* year; 30 human years=1 *pitṛ* year; 12 *pitṛ* years=1 *divya* year (divine year); 12,000 *divya* years constitute a *yuga* (6, 7, 8); the first half of the *yuga* is *utsarpiṇī kālā*, and the latter half is *avasarpiṇī kālā* and they are calculated from the apex of the Moon (*candrocca*) (this is not very clear) (9); a *yuga* is of 60 years, and such 60 *yugas*, that is 3,600 years had passed away since the *kaliyuga*, when the author was of 23 years of age, (10); the count of a *yuga*, year, month and

षडुच्छ्वासान् करोति, तावान्कालश्चार्द्धी विनाडिका स्यात् ।
(परमादीश्वर)

Just as we have the time division, similarly we have the *kṣetra* division or the circular angular division. A year has twelve months, so do we have 12 *rāśi* in a *bhagana*. One-thirtieth of a *rāśi* is one *bhaga*; one-sixtieth of a *bhaga* is one *lipta*; one-sixtieth of a *lipta* is one *vilipta*; and one-sixtieth of a *vilipta* is one *tatpara*.

३. चन्द्रोऽसौ द्वादशभिर्विद्विप्तोऽर्कान्तरस्थितैर्ह रयः ।
नवभिर्गुप्तुर्गोस्तैर्धधिकैर्यथाश्लक्ष्णाः ॥

—Ārya. IV. 4.

day should begin from the month *Caitra*, *Śukla Pratipadā* (the first day of the brighter half of the month *Caitra*) (11); *mandocca* (apex of slowest motion) and *śighrocca* (apex of fastest motion) (17—24).

(iv) The *Gola Pāda* with 50 verses. In Verse 1, there is a reference to a point in the Sun's path, the commencement of *meṣa* (*meṣādi*); this must have been *vasanta*-equinox. The ascending nodes (*pāta*) of planets and the shadow of the Earth move on the path of the Sun (*arka-apamaṇḍala*) (2-3); the angular difference in relation to the Sun at the appearance of Moon (12 degree or *aṁśa*), of the Venus (9 degrees or 9 *vināḍikā*); of the Jupiter (2 more than the Venus, i.e. 11 *vināḍikā*s); the Mercury or *Budha* (13 *vināḍikā*s), of the Saturn or *Śani* (15 *vināḍikā*s); and of Mars or *kuja* (17 *vināḍikā*s).

The half of the Earth, Moon, planets and stars is dark, since those parts happen to be under their own shadow; the other half is bright as it faces the Sun (this is not true with respect to stars—author) (5). The Earth is surrounded with an atmosphere of air and water (6, 7). In the *Brahma-Divasa* (Brahma's day), the sphere of the Earth is increased by one *yo'ana* and decreased by this amount during the Brahmā's night (8). Just as a person sitting on a moving boat sees the stationary trees etc. on the bank of a river moving in the opposite direction, similarly the stationary stars are seen moving from *Lankā* (or equator) moving towards the West (9). On account of *pravahavāyu* (air) the *nakṣatra* system and planets rise and set receding towards the West (10). The dimensions of *Sumeru Parvata* (North pole) is given to be one *yojana*, and it shines like a jewel (11) and in the next verse is given the position of *Sumeru* and the *Bāḍa-vamukha* (South pole) (12). The four cities situated at a difference of 90° each on the equator are given (13). The distance of *Ujjayini* from *Lankā* (thus giving the latitude of *Ujjayini*) is given (14).

On account of the thickness of the Earth-sphere, the *Khagola* (celestial sphere) is seen less than the hemisphere (15). The next verse describes how moving appears the *Khagola* on the North and South poles (16). Then is given the measure of day and night of *devas* (gods), *pitar* (fathers), *asura* (demons) and *manuja* (men) (17). Then are given a few technical definitions

of celestial mathematics (18—21) like *dyṣṭi-sthāna* (intersection of horizontal and vertical axis—*pūrvapardiggatā rekhā* and *adhar-urdhva-diggatā rekhā*). *Dṛṣṭi-maṇḍala*, *dyṅkṣepamaṇḍala* (*dyṅkṣepa* is the zenith distance of that point of a planet's orbit which is at the shortest distance from the zenith). Then the *Bhūbhagola* instrument is described (22, 23). Then follow the formulæ for calculating *lagna* (the horizon ecliptic point in the East), *kula* etc. comprising the *Tripraśnādhikāra* (24—33). In the next verses, we have *lambaka* or Rsine of colatitude (34); *dyṅk-karma* (35) and *ayana-dyṅk-karma* (36). Then follow the calculations of lunar and solar eclipses (37—47). Verse 48 describes the coordinates of the Sun which are determined by the conjunction of horizon with the Sun, of the Moon by the conjunction of the Sun and the Moon, of planets by the conjunction of the Moon and planets or stars. Verse 49 describes how this jewel treatise has been procured out of an ocean of true and untrue knowledge with the help of a boat of intellect. This means that the author has taken special pains in discriminating true knowledge from falsehood with respect to the prevalent notions of astronomy. In the last verse he says that he has not given anything new; he has given that very knowledge which was imparted by the *Svayambhu* in the earliest times (50).

The *Pañchāṅgas* prepared according to the rules and formulæ of the *Āryabhaṭīyam* are still regarded with reverence by the *Vaiṣnavas* in the South. Brahmagupta was a great critic of Āryabhaṭa, but finally he wrote his treatise, the *Khaṇḍakhadyaka*, on the basis of this very *Āryabhaṭīya* (this treatise is a *karaṇa-grantha* i.e. one containing a principal element of the Indian Calendar). The four commentaries of the *Āryabhaṭīya* available in Sanskrit are of Bhāskara I, Sūryadeva Yajvā, Parameśvara and Nilakantha. Two English translations by P.C. Senagupta (1927) and W.E. Clark (1930) are also available.

Major Landmarks

Indian astronomy which reached its zenith in the times of Āryabhaṭa and Brahmagupta shows its evolution in the following stages:

1. Rudiments of astronomy in the *Vedas* and *Brahmana*. Books like the *Taittirīya Samhita* and the *Śatapatha Brahmana*. This period is associated with the dis-

covery of the Vedic era, some of the planets, the twenty-four *nakṣatras*, cycle of seasons, concept of leap year, the dimensions of a yuga, solar and lunar years and the like.

- II. Astronomy of the *Vedāṅga*, also known as the *Vedāṅga Jyotiṣ*. Lagadha is the most prominent figure of this period (1400 B.C. to 850 B.C.) ; he is the first compiler of a text on astronomy. In his work, we for the first time in history find a reference to the *Jñeya Rāsi* (the knowable or the unknown quantity) and the *Jñāna-Rāsi* (known quantity). He lays the foundations of astronomical calculations. In his treatise we find a mention of such subjects as : Solstices (northern and southern journey of the Sun), increase in days and nights in the *ayanas* or solstices, solstitial *tithis* omission of *tithis*, *parva rāsi*, acceptable and non-acceptable *parvas*, addition of day, acceptable *parvas*, concept of *yoga* (a term applied to the joint space which would be travelled by the Sun and the Moon in a given period of time on the presumption that these two bodies have travelled in directions opposite to each other), method of finding out a *nakṣatra* on any *parva* day, distinction between *parva-nakṣatra* and *tithi-nakṣatra*, correlation of solar and lunar dates, measure of a *nādikā* (unit of time), *nakṣatra* of the Sun, *yoga* and its *nakṣatra*, *parva-bhaṣeṣa* and equivalent *kalās*, solar year, lunar revolutions (risings of *nakṣatras*) deities of *nakṣtras*, lunar and *sāvana day* differences (*ahika māsa*), divisions of a *sāvana day* and length of day in two *ayanas*. This author probably belonged to Kashmir.
- III. The period of *Siddhāntas* : Varāhamihira in his well known treatise, the *Pañcasiddhāntikā*, refers to five *Siddhāntas* or systems of Astronomy : Paitāmaha, Vasiṣṭha, Romaka, Pauliśa and Sūrya (Saura). As regards its importance, he gives the first place to the Sūryasiddhānta, places next the Romaka and Pauliśa, and declares the remaining two to be definitely inferior to the former. We do not possess the full treatise of these *Siddhāntas*, except the *Sūryasiddhānta*. Here too,

we have difficulty. The *Sūryasiddhānta*, as summarised by Varāhamihira in his *Pañcasiddhāntikā*, in many essential features differs from the system prescribed by the Text of the *Sūryasiddhānta* now available. So we have two versions, the one with which Varāhamihira was familiar and the modern one.

The present *Sūryasiddhānta* comprises of fourteen chapters called *adhyaṃyās*. We have an authentic commentary on it by Parameśvara. The first two chapters of the *Sūryasiddhānta* have no special name. The classification of chapters is as follows :

Modern Sūrya Siddhānta

Chapter	Name of the Chapter	Number of verses	Subject
I	—	69	Mean longitude of planets.
II	—	68	True motion and true longitude of planet ; and elements of <i>Pañcāṅga</i> .
III	Tripraśnādhyāya	50	Directions, place and time.
IV	Candra-grahaṇādhyaṃyāya	29	Lunar eclipse.
V	Sūrya-grahaṇādhyaṃyāya	17	Solar eclipse.
VI	Chedyakādhyāya	24	Projection of eclipse on a plane surface.
VII	Graha-samāgama-yuddhādhyāya	24	Conjunction of one planet with another.
VIII	Tārāviśayodhyāya	21	Conjunction of a Planet with the junction star of a nakṣatra.
IX	Udayāstamaya-viśayodhyāya	18	Heliacal rising and setting of planets.
X	Candrāstamayādi viśayāḥ	16	Moon rise and elevation of Moon-horn.
XI	Vyatipāta-viśayāḥ	23	Pāta (<i>vyatipāta</i>)
XII	—	87	Cosmogony and geography

Chapter	Name of the Chapter	Number of verses	Subject
XIII	Vyatipāta-viṣayāḥ	26	Armillary sphere and astronomical instruments
XIV	—	28	Modes of reckoning time
	Total	500	

From the contents of the Modern *Sūryasiddhānta*, it appears that its great author (or rather *compiler*, since this *Siddhānta* has been existing much before he compiled this treatise) intends giving a complete but brief account of the entire Indian astronomy. He has been careful enough to avoid controversies, and he has omitted the methods occurring in other *Siddhāntas* and *Mahā-tantras* as alternative rules. He describes only those which are most important and of general nature. Part II of the book dealing with cosmogony and geography etc., is very brief, and the entire subject has been summarised in three chapters (Chapters XII to XIV). The Chapter on Astronomical instruments (XIII) is sketchy and rather incomplete; the author has given the names only of the instruments, as if the purpose was to keep the details secret and guarded. The whole text of the *Sūryasiddhānta* is finished in 500 verses (compare this with the length of other Indian books on Astronomy: the *Brāhmasphuṭasiddhānta* 1008 verses, the *Siddhānta-sekhara* 890 verses and *Siddhānta-siromaṇi* proper 962 verses).

The Modern *Sūryasiddhānta* is a composition or compilation of a period when the *Āryabhaṭīyam* and the *Brāhmasphuṭasiddhānta* had already become popular. This *Sūryasiddhānta* is indebted to both these systems, though it has nowhere acknowledged them in the Text. We shall refer to this matter later at an appropriate stage of our discussion.

It may casually be mentioned here that Alberuni has ascribed the authorship of the *Sūryasiddhānta* to Lāṭādeva while Munīśvara (603 A. D.) has ascribed it to Āryabhaṭa I. Though there is little or no support to these views, it is not improbable, that the works of Āryabhaṭa I and Lāṭādeva which followed mid-night-day-reckoning were based on the *Sūryasiddhānta* prevalent at the time. P. C. Senagupta on the other hand is of the opinion that "the old *Sūryasiddhānta* was made up-to-date by Varāhamihira by replacing the old constants in it by new ones from Ārya-

bhaṭa I's midnight system. " In this connection, it must be remembered that Varāhamihira nowhere expresses his indebtedness to Āryabhaṭa I.

The *Sūryasiddhānta* undoubtedly is the most popular book on Astronomy in this country. It has been so for the last 1000 years as is seen from the list of commentators on its text (K. S. Sukla has given a list of 28 commentators including those who wrote commentaries in the South Indian languages like Telugu and Kannaḍa.):

Allanarya Suri	Maheśvara
Amareḍya	Mallikārjuna Suri (1178 A. D.)
Bhaṭṭotpala (966 A. D.)	Nārāyaṇa
Bhūdhara (1572 A. D.)	Nrsinha Daivajña (b. 1586 A.)
Bhūti viṣṇu	Nṛsiṃhadeva
Caṇḍeśvara (1178)	Parameśvara (1432 A. D.)
Cola	Raghava Śarmā (1592 A. D.)
Dādābhai (1719 A. D.)	Ramakṛṣṇa Ārādhyā (1472 A. D.)
Devidāsa	Raṅganātha (1603 A. D.)
Kamala Kara Daneśvarah (1618 A. D.)	Sārvabhauma
Kāmabhaṭṭa	Tamma Yajva (1599 A. D.)
Kṛṣṇa Daivajña	Yallaya (1472 A. D.)
Madanapāla	Viśvanātha (1628 A. D.)
Mādhavācārya	

A large number of astronomical books in this country were written on the basis of the *Sūryasiddhānta*, as the *Gaṇakananda* by Sūrya (1387-1447 A. D.), *Gaṇitadarśa* by Dharmapathin, *Makaranda Sārīṇi* by Makaranda (1478 A. D.), *Grahaçakra* by Kucanācārya (1299 A.D.), *Viṣṇukaraṇa* by Viṣṇu (1556 A.D.) besides many others with indefinite dates such as the *Sūryasiddhānta nayana-prakārah*, *Sūryasiddhānta-gaṇita Sūryasiddhānta-saṃgraha* by Viśvanātha Suri, and *Sūryasiddhānta Sārīṇi* by Rāmadatta Daivajña. K. S. Sukla has given a list of this literature in his Introduction to the *Sūryasiddhānta*.

(iv) *Period of Bhāskara I*: The author or the compiler of the *Sūryasiddhānta* is not known nor its date of composition. Bhāskara and Brahmagupta are the brilliant names of a contemporary period. Bhāskara I lived in the seventh century of the Christian era and was a contemporary of Brahmagupta (628

A.D.). He wrote three works on Astronomy which were most likely composed in the following order : (i) the *Mahā-Bhāskariya*. (ii) a commentary on the *Āryabhāṭiya*, and (iii) the *Laghu-Bhāskariya*. His commentary on the *Āryabhāṭiya* was written in 629, i.e., only one year after the *Brahmasphuṭasiddhānta*. His commentary on the *Āryabhāṭiya* was written in 629 A.D., i.e., one year after the completion of the *Brahmasphuṭasiddhānta*. Undoubtedly Bhāskara was the follower of Āryabhata I. Shukla says, that his works provide us with a detailed exposition of the astronomical methods taught by Āryabhata I and throw light on the development of Astronomy in India during the sixth and early seventh centuries A. D. which was the most brilliant period in the history of Indian Astronomy-Shukla has brought a critical edition with English translation of the *Mahābhāskariya* and the *Laghu-Bhāskariya* and he proposes to bring out a volume on the life and works of this great astronomer,

Division of Mahābhāskariya

The *Mahābhāskariya* is divided into Chapters called the *adhyāyas*. The *adhyāyas* have not been named as some of the Chapters of the *Sūryasiddhānta* or the *Brahmasphuṭasiddhānta*. The number of verses in the *Mahābhāskariya* is as follows :

	Subject	Number of verses
Adhyāya I	Mean Longitude of a Planet and Planetary Pulveriser	52
Adhyāya II	The Longitude Correction	10
Adhyāya III	Direction, Place and Time. Junction-stars of the Zodiacal Asterisms and conjunction of Planets with them.	75
Adhyāya IV	The Longitude of a Planet	64
Adhyāya V	Eclipses	78
Adhyāya VI	Rising, Setting and Conjunction of Planets	62
Adhyāya VII	Astronomical Constants	35
Adhyāya VIII	Examples	27

These titles to the subject-matter given in the above table have been assigned by Dr. Kripa Shanker Shukla in his critical

edition. The total number of verses in this work is 403. The *Sūryasiddhānta* has, as stated above, 500 verses in all.

Laghu-bhaskariya

The *Laghu-Bhāskariya* is also divided into eight chapters, each chapter is known as *Adhyāya*. The subject matter in the book has been dealt with as follows :

Subject			Number of verses
Adhyāya	I	Mean longitudes of the Planets	37
Adhyāya	II	True Longitudes of the Planets	41
Adhyāya	III	Direction, Place and Time from Shadow	35
Adhyāya	IV	The Lunar Eclipse	32
Ādhyāya	V	The Solar Eclipse	15
Adhyāya	VI	Visibility, Phases and Rising and Setting of the Moon	25
Adhyāya	VII	Visibility and Conjunction of the Planets	10
Ādhyāya	VIII	Conjunction of a Planet and a Star	19

The total number of verses in this text is 214. The *Laghu-Bhāskariyam* is thus an abridged edition of the *Mahā-Bhāskariyam*. From the closing stanza of this work, it is clear that the author wrote this work for the benefit of young students with immature mind by condensing and simplifying the contents of his larger work, the *Mahā-Bhāskariyam* (also known as *Karma-nibandha*). Thus we have a little of the parallelism: Brahmagupta, after finishing his bigger treatise, the *Brahma-sphuṭasiddhānta*, wrote a minor abridged work, the *Khaṇḍa-khādyaka*, as a *karana-grantha*. This latter work of Brahmagupta, however, incorporates some original ideas not included in the earlier work. Shukla has given an analytical table indicating the rules of the *Mahā-Bhāskariyam* incorporated in the *Laghu-Bhāskariyam* also in an abridged or modified form, and also a list of the rules which have been omitted in the *Laghu-Bhāskariya*. There are a few rules in the *Laghu-Bhāskariya* also which have no counterpart in the

Mahā-Bhāskariya. Shukla further says that the arrangement of the contents of the *Laghu-Bhāskariya* is more systematic and logical than that of the *Mahā-Bhāskariya*, and is, at the same time, in keeping with the general practice followed by the other Hindu astronomers. Numerous quotations of this work occur in the annotative works of Sūryadeva (b. 1191 A.D.), Yallaya (1480 A.D.), Nilakaṇṭha (1500 A.D.), Raghunātha Rāja (1597 A.D.), Govinda Somayāji and Viṣṇu Śarmā and in the *Prayogaraśanā*, an anonymous commentary on the *Mahā-Bhāskariyam*. We find the commentaries of this abridged work in Malayalam and Tamil also. All this speaks of the great popularity of this work.

There are circumstantial evidences to show that Bhāskara I had associations with the countries of Aśmaka and Surāṣṭra. His commentary on the *Āryabhaṭiya* was probably written in the city of Valabhī in Surāṣṭra. Perhaps Bhāskara I was born and educated in Aśmaka and later on he migrated to Valabhī, where he wrote his commentary on the *Āryabhaṭiya* or that he was a native of Valabhī and got his education in the Aśmaka country. Perhaps there was a strong school of Astronomy in the Aśmaka country, which was founded by the followers of Āryabhaṭa, so much so that at places, Bhāskara I has also called Āryabhaṭa as Āśmaka, his *Āryabhaṭiyan* by the name *Aśmaka-Tantra* or the *Āśmakiya* and the followers of Āryabhaṭa as *Āśmakiyāḥ*. This Aśmaka country or Aśmaka Janapada is mentioned in the Buddhist literature also. It was somewhere either in the north-west of India, or was situated between the rivers Narmadā and Godāvari. Bhāskara I was evidently a resident of the latter Aśmaka (which was between the Narmadā and Godāvari).

Brahmagupta and Bhāskara I were contemporaries. Both of them developed their systems in the earlier part of the seventh century A.D. (3700 years of *Kaliyuga*). *Brahmasphuṭasiddhānta* was written in 628 A.D. and the commentary on the *Āryabhaṭiyan* by Bhāskara I was composed in 629 A. D. Bhāskara closely followed Āryabhaṭa, but Brahmagupta had the guts to oppose the views expressed by this great master and he not only contradicted him at places, but also propounded many new ideas, methods of calculation and constants of greater accuracy.

The classification of the contents of Astronomy in *adhikāras* appears to be the original concept of *Brahmagupta*; this system was to some extent adopted in the modern *Sūrya-Siddhānta* in the case of a few chapters. The *Vaṭeśvara-Siddhānta* by Vaṭeśvarācārya (born 802 Śaka or 880 A.D. in Ānandapura city, Punjab, son of Mahādatta) also adopts the terminology: *Madhyamadhikāra*, *Spaṣṭādhikāra* and *Tripraśnādhikāra*. We owe this type of caption-nomenclature to Brahmagupta.

Contents of the Brahmasphuṭasiddhānta

Now we shall summarise the contents of the Chapters of this great treatise and also enumerate the number of verses in each chapter. The author has himself given the total number of verses in the Chapter in the ending verse of each chapter. Sometimes, the verse specifying this number itself is not taken into account while giving the total number of verses in that chapter, and therefore, there occurs a minor discrepancy in the actual number and the number specified by the author himself. The following table records both these numbers separately :

Chapter	Title	Number of verses indicated by the author	Actual number of verses
PŪRVA-DAŚĀDHYĀYI (First Ten Chapters)			
I	Madhyāmadhikārah (Madhyamagati-radhyāyah)	63	63
II	Spaṣṭādhikārah (Sphuṭagati-radhyāyah)	67	68
III	Tripraśnādhikārah (Tripraśnādhhyāyah)	66	66
IV	Candragrahaṇādhikārah (Candragrahaṇādhhyāyah)	20	20
V	Sūryagrahaṇādhikārah (Ārka-grahaṇam or Ravigrahaṇādhhyāyah)	26	27
VI	Udayāstādhikārah (Udayāstamayādhhyāyah)	12	13

VII	Candraśṛṅgonnatyadhikārah (Candraśṛṅgonnati-adhyāyah)	18	18
VIII	Candracchāyādhikārah (Candracchāyā-adhyāyah)	9	9
IX	Grahayutyadhikārah (Grahamelanādhhyāyah)	26	26
X	Bhagrahayutyadhikārah (Bhagrahayutiḥ-adhyāyah)	70	70
	Total (of Daśādhyaī)	377*	380*
XI	Tantra-Parikṣādhyaīyah (Dūṣaṇādhyaīyah)	63	63
XII	Gaṇitādhyaīyah Miśraka-vyavahārah 1—16 Śreḍhī-vyavahārah 17—20 Kṣetra-vyavahārah 21—39 Vṛttakṣetra-gaṇitam 40—43 Khāta-vyavahārah 44—46 Citi-vyavahārah 47— Kākacika-vyavahāre karaṇasūtre 48—49 Rāśi-vyavahārah 50—51 Chāyā-vyavahārah 52—66	66	66

XXII	Yantrādhyāyaḥ	53	57
XXIII	Mānādhyāyaḥ	12	12
XXIV	Sañjñādhyāyaḥ	13	13
	Total	1016	1022

In one of the verses, Brahmagupta states that he has composed the treatise containing 1008 verses. Sudhākara Dvivedī has given the total as 1021, whereas he says, this number according to Brahmagupta's own statement should be 1020. If one deducts the concluding 12 verses of the *Sañjñanādhyāya*, the number should be 1008.

Sudhākara Dvivedī, in his addition of the *Brahma-sphuṭa-siddhānta* (published in the *Pañḍita*, 1901 and 1902) gives as a supplement a small treatise of Brahmagupta known as *Dhyānagrahaṇopadesādhyāya* or *Dhyānagrahaṇādhikāraḥ* which has 72 verses.

It would be worthwhile to give here the details of the *Khaṇḍakhādyaka* also, a book of Brahmagupta about which we have spoken so much. The titles to the chapters have not been indicated in the Text; most likely they have been assigned by the commentator, Pṛthūdaka Svāmī known as the *Khaṇḍakhādyaka-vivaraṇam*.

Chapter	Title	Number of verses
I	Tithi-nakṣatrādhikārādhyaḃayaḥ (On tithis, nakṣatras etc.)	32
II	Grahagatyadhyaḃayaḥ (On the mean and true places of 'star' planets)	19
III	Tripraśnādhyaḃayaḥ (On the three problems relat- ing to diurnal motion)	16
IV	Candragrahaṇādhyaḃayaḥ (On lunar eclipses)	7
V	Suryagrahaṇādhyaḃayaḥ (On solar eclipses)	6
VI	Udayāstādhikārah (On the rising and setting of planets)	7
VII	Candrasṅgonnatyadhāyaḥ (On the position of the Moon's cusps)	4
VIII	Samāgamādhyaḃayaḥ (On conjunction of planets)	6
UTTARA KHAṆḌAKHĀDYAKA—APPENDIX		
IX	Corrections and new methods	14
X	On conjunction of stars and planets	16
Total		127

Bhaṭṭotpala, in his commentary on the *Khaṇḍakhādyaka* has given several additional verses in the main or proper treatise and also in its Uttara portion or the Appendix. P.C. Sengupta's edition (Sanskrit Text 1941) has given at the end of this publication the account of these additional verses. The English

edition (1934) classifies the *Uttara-Khaṇḍakhadyaka* into two chapters (which the author calls as Chapters IX and X), the Sanskrit edition gives 3 verses in Chapter IX, 21 verses in Chapter X and 24½ verses in Chapter XI. Of these three chapters, the Chapter X has been given the title "*Paṭadhikara*" and Chapter XI the title "*Parilekhādhyāya*" by Bhaṭṭotpala.

Āryabhata and Brahmagupta Controversy

The scientific Indian astronomy was more or less created by Āryabhata I (476 A. D.). It is said that he was the teacher of two distinct systems of astronomy, one of which is called the *audayika* system, and the other the *ardharātri* system. In the first, the astronomical day is taken to begin at *sunrise* at Lānkā, and in the other, the same begins at the *midnight* of the same place. In the *Khaṇḍakhādya* Brahmagupta gives compendious rules for the calculation of longitudes, etc, of planets according to the *ardharātri* system of Āryabhata I. In this connection, he refers to Āryabhata in the following words in his *Khaṇḍakhādya* :

Having made obeisance to God Mahādeva, who is the great cause of this world's rise (i. e. creation), existence, and destruction, I shall declare the *Khaṇḍakhādya* which will yield the same results as the great astronomical treatise of Āryabhata.¹

As in most cases calculation by the great work of Āryabhata, for (the knowledge of time and longitude of planets etc. at) marriage, nativity and the like is impracticable for common use every day, this smaller

1. प्रणिपत्य महादेवं जगदुत्पत्तिस्थितिप्रलयहेतुम् ।
वक्ष्यामि खण्डखाद्यकमाचार्यार्यभट्टतुल्यफलम् ॥

treatise (i.e. *Khaṇḍakhādyaka*, literally meaning food prepared from sugar-candy) is made so as to yield the same results as that.¹

The mean saturn diminished by 3 seconds, the *Śighrocca* of Mercury diminished by 22 seconds, the mean Mars increased by 2 seconds and the mean Jupiter increased by 4 seconds are equal to the respective mean planets of Āryabhaṭa's *midnight* system.²

In the *Brāhmasphuṭasiddhānta*, Brahmagupta accepts the astronomical day to begin with the sunrise at Lankā, and the calculations of days, months, years, Yugas, and Kalpas all begin from Caitra Śukla Pratipadā (the first *tithi* of the month Caitra in the bright-half of the Moon) and the first day is regarded as Sunday.³

Varāhamihira in his epicyclic cast to the *Sūryasiddhānta* in his *Pancasiddhāntikā* adopts the *ardharātri* system or the system of reckoning days from midnight. The question why Brahmagupta who was so bitter an opponent of Āryabhaṭa I in his younger days (628 A.D.) claimed down to describe and teach one of the systems of Āryabhaṭa's astronomy in his sixty-seventh year (665 A.D.) is difficult to explain. In fact so great was Āryabhaṭa's reputation and fame that in spite of Brahmagupta's severe ricticisms of the former in Chapter XI of the *Brāhmasphuṭasiddhānta*, it perhaps was undiminished and it was Āryabhaṭa who continued to be universally followed.

Some authorities have thus expressed the view that to meet the popular demand Brahmagupta in the *Khaṇḍakhādyaka* took upon himself the task of simplifying Āryabhaṭa's *ardharātri* system and in this task he became eminently successful. But it has been supposed that in this task he could not be a mere simplifier or expounder.

॥ अत्रसितादेष्टयाद्भानोर्दिनमासवर्षयुगकल्पाः ।

सूच्यादौ लंकायां समं प्रवृत्तः दिनेऽर्कस्य ॥

—BrSpSi I. 4

The minor work of Brahmagupta known as *Khaṇḍakhādyaka* has two distinct parts : *Khaṇḍakhādyaka* proper and the *Uttara Khaṇḍakhādyaka*. In the first part the astronomical constants are the same as those of Āryabhaṭa's *ardharātri* system, but the methods of spherical astronomy, calculation of eclipses and other topics are almost the same as in the *Brāhmasphuṭasiddhānta*. The corrections for parallax in calculating a solar eclipse is here an important illustration.¹

In the *Uttarakhaṇḍakhādyaka*, Brahmagupta gives corrections to the *Khaṇḍakhādyaka* proper. In it are to be found the neat and original methods of interpolation and correction to the longitudes of the aphelia, as also to the dimensions to the epicycles of apsis of the Sun and the Moon.² while a few additional chapters supply what else is necessary to the first seven chapters of the first part, to make the whole a complete treatise on Indian scientific astronomy. It was perhaps through the influence of this supplementary part of the *Khaṇḍakhādyaka* that Brahmagupta's great work, the *Brāhmasphuṭasiddhānta* came to be valued among a distinct school of Indian astronomers. For long in this country India, this *Siddhānta* of Brahmagupta has been forming the basis for the calculation of almanacs by astronomers of the orthodox school of Rājasthān, Bombay and others.

We might at this stage take up the question : Was Āryabhaṭa the author of two distinct systems of astronomy ? Undoubtedly he was. Several authors have written on this subject. I may specially mention the name of Prabodha Chandra Sengupta (*Journal of the Department of Letters, Calcutta University*, vol. XVIII; *Bulletin, Calcutta Mathematical Society*, vol. XXII. Nos. 2 and 3). The reasons advanced by him may be restated in slight details thus. In his *Brāhma-*

1. व्यासार्धेन विभक्ता दृग्गतिर्जीवा चतुर्गुणा लब्धम् ।

—*BrSpSi*. XI. 23-25, also *KK*. V.

2. See *UKK*. 9.

sphuṭasiddhānta, Brahmagupta thus speaks of the two works of Āryabhata:

As in both the works the number of the Sun's revolutions is spoken of as 432,000 years, their planetary cycle is clear, i. e., of 4,320,000 years. Why then is there difference of 300 civil days in the same cycle of the two books ?¹

Again, he says :

In 14,400 years elapsed of the *Mahāyuga*, there is produced a difference of one day in the *audayika* and *ardharātri* systems.²

Varāhamihira in the *Pañcasiddhāntikā* writes :

Āryabhata maintains that the beginning of the day is to be reckoned from midnight at Lankā; and the same teacher again says that the day begins from sunrise at Lankā.³

Thus from the writings of Brahmagupta and Varāhamihira, it is clear that Āryabhata I was the author of both the *audayika* and *ardharātri* systems of astronomy. In Varāhamihira's verse the phrase *sa eva* (स एव), meaning "he undoubtedly" is of special significance. It removes the least doubt as to Āryabhata's authorship of both these systems. The *audayika* and *ardharātri* astronomical constants are respectively to be found from the Āryabhatīya and may be deduced from the *Khaṇḍakhādyaka* as well. The following is the comparative view of the constants of Varāhamihira and of the present day *Sūrya-siddhānta*.

TABLE I

The *Mahabhāskariya* of Bhāskara I (522 A. D.) contains a passage which corroborates the fact that Āryabhaṭa I was the author of both the *audayika* and the *ardharātri* systems of Indian Astronomy. According to Pṛthudakasvāmin, whose

commentary on the *Brāhmasphuṭasiddhānta* we have the privilege of presenting to the public, it is clear that in certain respects Bhāskara and others may be wrong but the Āryabhāṭa's authenticity cannot be questioned. Pṛthudakasvāmin while commenting on the *Brāhmasphuṭasiddhānta*, XI. 26 writes:

Such a mistake may have been made by Bhāskara and others; they have not understood his (Āryabhāṭa's) intention.

The passage in the *Mahābhāskariya* giving constants of the *ardharātri* system runs as follows (we are giving the translation from Kripa Shankar Shukla's edition on the *Mahābhāskariya*) :

The astronomical processes which have been set forth above come under the sunrise day - reckoning (*audayika* system). In the midnight day-reckoning (*ardharātri* system) too, all this is found to occur: the difference that exists is being stated (below).¹

The next fourteen stanzas relate to the midnight day-reckoning of Āryabhāṭa I.

- (i) Civil days and omitted lunar days in a *yuga* and revolution numbers of Mercury and Jupiter are thus given :

(To get the corresponding elements of the midnight day-reckoning) add 300 to the number of civil days (in a *yuga*) and subtract the same (number) from the number of omitted lunar days (in a *yuga*); and from the revolution numbers of (the *sihrocca* of) Mercury and Jupiter subtract 20 and 4 respectively.²

Thus according to the midnight day-reckoning, we get

civil days in a <i>yuga</i>	= 1,577,917,800
omitted lunar days in a <i>yuga</i>	= 25,082,280
revolution number of the <i>sihrocca</i> of	
Mercury	= 17,937,000
revolution number of Jupiter	= 364,220

1. निबन्धः कर्मणां प्रोक्तो योऽसावौदयिको विधिः ।

अर्धरात्रे त्वयं सर्वो यो विशेषः स कथ्यते ॥

—MBh. VII. 21

2. त्रिशती भूदिने क्षेप्या ह्यवमेभ्यो विशेष्यते ।

॥ गुर्वोमेगयेभ्योऽपि विंशतिश्च ततोऽन्वयः ॥

—MBh. VII. 22

- (ii) Diameters of the Earth, the Sun and the Moon are thus given :

(In the midnight day-reckoning) the diameter of the Earth is (stated to be) 1,600 *yojanas*; of the Sun 6,480 (*yojanas*) and of the Moon, 480 (*yojanas*)¹.

- (iii) Mean distances of the Sun and the Moon are as follows :

The (mean) distance of the Sun is stated to be 689,358 (*yojanas*), and of the Moon 51,566 (*yojanas*).²

- (iv) Longitudes of the apogees of the planets are as follows: 160, 80, 240, 110, and 220 are in degrees the longitudes of the apogees of Jupiter, Venus, Saturn, Mars and Mercury respectively.³

- (v) *Manda* and *Śighra* epicycles of the planets are as follows :

The *Manda* epicycles (of the same planets) are 32, 14, 60, 70, and 28 (degrees) respectively; and the *Śighra* epicycles are 72, 260, 40, 234, and 132 (degrees) respectively. The Sun's apogee and epicycle are the same as those of Venus (i. e. 80° and 14° respectively).

The Moon's epicycle in the midnight day-reckoning is stated to be 31 (degrees).⁴

- (vi) The positions of the so called *manda* and *śighra pātas* of the planets are given below:

(The following directions for) the degrees of the (*manda* and *śighra*) *pātas* of the planets as devised

(under the midnight day-reckoning) should be noted carefully by learned scholars :

Add 180° to the longitudes of the *mandoccas* (apogees) and *sihroccas* of Mercury and Venus, and subtract 3 signs from the *mandoccas* (apogees) and *sihroccas* of the remaining planets. Then are obtained the longitudes of the *manda* and *sihra pātas* of the planets. (Also) add 2 degrees to the longitudes of the *manda pātas* and *sihroccas* of Venus, Saturn and Jupiter, and $1\frac{1}{2}$ degrees to those of Mars and Mercury. (It should be noted that) the *sihra pātas* have been stated for all the planets excepting Mercury. (Mercury does not have a *sihra pāta*).¹

That is to say, the longitudes of the *manda pātas* of Mars, Mercury, Jupiter, Venus, and Saturn are 21.5, 41.5, 72, 262 and 152 degrees respectively; and the longitudes of the *sihra pātas* of Mars, Jupiter, Venus and Saturn are (*sihrocca*— 88.5°), (*sihrocca*— 88°), (*sihrocca*+ 182°) and (*sihrocca*— 88°) respectively.

(vii) A rule for finding the celestial latitude of a planet is as follows :

(From the longitude of a planet severally) subtract the longitudes of its (*manda* and *sihra*) *pātas* and therefrom calculate (as usual) the corresponding celestial latitude of that planet. Add them or take their difference according as they are of like or unlike directions. Then is obtained the true celestial latitude of that particular planet. The true celestial latitude of any other planet is also obtained in the same way. The remaining (astronomical) determinations are the same as stated before. This all is in brief the difference of the other *tantra* (embodying the midnight day-reckon-

-

| विबुधानां च सर्वेषां शीघ्रपाताः प्रकीर्तिताः । | |

ing of Āryabhaṭa I).¹

(viii) A rule for finding the longitude of the true mean planet according to midnight-day reckoning is as follows :

Apply half the *Sighraphala* and (then) half the *mandaphala* to the longitude of the planet's own *mandocca* (reversely).

From the resulting longitude of the planet's *mandocca* calculate the (*mandaphala* and apply it to mean longitude of the planet : the resulting longitude of planet is stated to be) the true-mean longitude of the planet. This is stated to be another difference (of the midnight day-reckoning) ²

(ix) Length of the circle of the sky and derivation of the lengths of the orbits of the planets are given as follows :

Multiply the revolutions of the Moon (in a *yuga*) by 3, 240,000 and then discard the zero in the unit's place : (this is the length of the circle of the sky in terms of *yojanas*). (Severally) divide that by the revolutions of the planets (in a *yuga*): thus are obtained the lengths of the orbits of the respective planets in terms of *yojanas*.³

From these stanzas (from 20-35), it is evident that one *yojana* of the sunrise day-reckoning is one and a half times that of the midnight day-reckoning.

Now from stanza 22, it appears that 300 is to be added to the number of civil days in a *Mahayuga*. According to the *Āryabhaṭīya*, the number of civil days in this cycle is 1,577,917, 500, which increased by 300, becomes 1,577,917,800, the number of

—MBh. VII. 35

civil days in a *Mahāyuga* according to Brahmagupta as referred to in the *Khaṇḍakhādya*.

Again, the same stanza tells us to subtract 20 and 4 respectively from the revolutions of Mercury and Jupiter, and we arrive at the figures 17,937,000 and 364, 220, which are the revolutions of Mercury and Jupiter in a *Mahāyuga* according to Brahmagupta as given in the *Khaṇḍakhādya*.

Again we can compare the figures for the diameters of the Earth, the Sun and the Moon given in the *Mahābhāskariya*, in the present day *Sūrya-siddhānta* and the *Āryabhaṭīya*.

Diameter of	<i>Mahābhāskariya</i>	Modern, <i>Sūrya-siddhānta</i>	<i>Āryabhaṭīya</i>
Earth	1,600 yojanas	1,600 yojanas	1,050, yojanas
Sun	6,480	6,500	4,410
Moon	480	480	315

Then in stanza 24, we are given the distances of the Sun and the Moon as 689, 358 and 51, 566 yojanas respectively. The same figures are worked out by Lalla according to the *Āryabhaṭīya* and quoted in the *Śiṣyadharmyādhikā* (IV.3.4) and they come to be 459,585 and 34,377.

The stanza 25 states the longitudes of the aphelia of planets these figures tally with the corresponding figures given by Brahmagupta in the *Khaṇḍakhādya* :

Longitude of aphelion of Jupiter 160°, of Venus 80°, of Saturn 240°, of Mars 110° and of Mercury 220°.

Similarly the stanza 26 gives the peripheries of planets' epicycle of apsis, which also is in concordance with the values given by Brahmagupta :

Periphery of epicycle of apsis of Jupiter 32°, of Venus 14°, of Saturn 60°, of Mars 70° and of Mercury 28°.

In the stanza 27 of the *Mahābhāskariya*, we have the dimensions of the epicycles of conjunction for planets; these figures are also the same as given by Brahmagupta :

Epicycles of conjunction for Jupiter 72°, for Venus 260°, for Saturn 40°, for Mars 234° and for Mercury 132°.

In the stanza 28, we have the Sun's epicycle having a periphery of 14° and the Moon's epicycle 31°; the longitudes of

the nodes of the planets to be the same as in the *Āryabhaṭīya*. All these are the same as given by Brahmagupta in the *Khaṇḍakhādyaka*.

In the stanza 33 we have rules for finding the geocentric longitudes of planets which may be taken to be the same as in the *Khaṇḍakhādyaka*¹; compare these values with those in the *Sūryasiddhānta* of Varāhamihira in the *Pañcasiddhāntikā*, XVII. 6, but slight different from the *Āryabhaṭīya*.²

The last stanza of the *Mahābhāskariya* (35) gives the dimensions in *yojanas* of the orbits of planets ; these are the same as in the modern *Sūryasiddhānta*.

Thus we find a great semblance in the constants as given by the *Mahābhāskariya* of Bhāskara I, of the *Sūryasiddhānta* as given by the *Pañcasiddhāntikā* and understood by Varāhamihira, and also the constants as given by Brahmagupta in his treatises, specially the *Khaṇḍakhādyaka*. It must not be forgotten that the same Āryabhaṭa I who is the celebrated author of the *Āryabhaṭīya* is also the author of another treatise very often referred to as the *Tantra*.

I shall quote Prabodha Chandra Sengupta in connection with these similarities, and the great influence of Āryabhaṭa on Indian Astronomy. He writes in his Introduction to the *Khaṇḍakhādyaka* as follows :

We have shown that there is much resemblance in the constants between the *Sūryasiddhānta* of Varāha and the *Khaṇḍakhādyaka* and for the matter of that with the *Tantrāntara* of Āryabhaṭa I. In my papers "Āryabhaṭa and Āryabhaṭa's Lost Work", I have established the fact that the *Sūryasiddhānta* as it existed before the time of Varāha, was made more accurate by him by borrowing the constants from Āryabhaṭa's *ardharātri* system. That there was a *Sūryasiddhānta*

१. शीघ्रफलाद्धं मध्ये मन्दफलाद्धं च मन्दशीघ्रफले ।

सकले मध्ये स्पष्टः शीघ्रं मध्योनकं केन्द्रम् ॥

—Arya. III. 23-24

before the time of Varāha, is seen from Section 6 of the Table on page xii given before. This point is made clear from another consideration, viz., the star table in the modern *Sūryasiddhānta*, which unmistakably points to the conclusion that the longitudes of some stars, e.g., Spica etc., correspond to a time much anterior to that of Āryabhaṭa I. The great fame of Āryabhaṭa I induced Varāha, the first maker of a *neo-Sūryasiddhānta* to use the elements of Āryabhaṭa's *ardha-rātri* system to supplant the older materials in it. No wonder, therefore, that there is an opinion in favour of the hypothesis that Āryabhaṭa I was the author of the *Sūryasiddhānta*. If there were a shadow of truth in it, Varāha would have admitted it. Alberuni indeed says that the *Sūryasiddhānta* was composed by Lāṭa (Alberuni's India, translated by Sachau, Vol. I. p. 153). We now know that this Lāṭa or Lāṭadeva was one of the first pupils of Āryabhaṭa I. He was the expounder of the Romaka and Pāuliśa *Siddhāntas* as we learn from Varāhamihira's *Pañcasiddhāntikā*, (I.3). As Alberuni's statement is not corroborated by Varāha, we are not inclined to take it as correct. None of the earlier writers suggest that the *Sūryasiddhānta* was in any way modified or changed by Āryabhaṭa I.

It has now been established beyond doubt that the same Āryabhaṭa was the author of the *Aryabhaṭīya* and another *Tantra* which is now lost. There is reason in support of hypothesis that this *Tantra* itself was the first work of Āryabhaṭa I and that the *Aryabhaṭīya* was the second work from the order in which Varāha mentions them in the Stanza quoted earlier. If this hypothesis be true, the stanza in the *Aryabhaṭīya*¹,

which was translated by me as :

"Now when sixty times sixty years and three quarter *yugas* also have elapsed, twenty increased by three years have elapsed since my birth."

1. षष्ट्यब्दानां षष्टिर्यदा व्यतीतास्त्रयश्च युगपादाः ।

अधिका विंशतिरब्दास्तदेह मम जन्मनोऽतीताः ॥

—*Ārya. III. 10.*

should now be translated thus :

"In this *Mahāyuga* when sixty times sixty years and three quarter yugas also had passed, twenty increased by three years had elapsed since my birth."

Now Bhāskara I the author of the *Mahābhāskariya* and the *Lagubhāskariya*, wrote a commentary on the *Āryabhaṭiya*. The author commenting on this stanza observes that :

"Or this was addressed by Āryabhaṭa when expounding the science to Paṇḍuraṅgasvāmin, Lāṭadeva Niḥśanku and other pupils."¹

This direct pupil of Āryabhaṭa I also says that this stanza does not show that the *Āryabhaṭiya* was composed when Āryabhaṭa I was only 23 years old, but refers to the time when he probably began his career as a teacher of Astronomy.

Senagupta out of his discussion concludes that we are not justified in accepting that the *Āryabhaṭiya* was composed when Āryabhaṭa was only 23 years of age. This treatise as it exists in the present form must have been the composition of a mature age; it is a treatise highly finished in form; the date mentioned in this great work refers to a date when its author became a reputed *guru* or teacher.

Alberuni and Brahmagupta

Dr. E.C. Sachau in his translation of Alberuni's India (vol. II. p. 304) speaks of Brahmagupta in the following words :

Brahmagupta holds a remarkable place in the history of Eastern civilization. It was he who taught the Arabs astronomy before they became acquainted with Ptolemy; for the famous *Sindhind* of Arabian literature, frequently mentioned but not yet brought to light, is a translation of his *Brahmasiddhanta*; and the only other book on Indian astronomy, called *Atarkand*, which they knew, was a translation of his *Khaṇḍakhādyaka*.

Brahmagupta, the celebrated author of the *Brāhmasphuṭa-siddhanta*, has another great work as we have said before to his credit which goes by the name *Khaṇḍakhādyaka*. This has

1. एतदेवाचार्यार्यभट्टस्य शास्त्रव्याख्यानं समये वा पाण्डुरङ्गस्वामिलाट्टदेवनिःशङ्कुप्रभृतयः प्रोवाच ।

already been said that perhaps to meet the popular demand. Brahmagupta in this treatise took upon himself the task of simplifying Āryabhata's *ardharātrika* system or the system of midnight day reckoning. Alberuni, the author of the *Indika* has made several references or quotations from the *Khaṇḍakhadyaka* proper and also its supplement, known as *Uttara-Khaṇḍakhadyaka*.

- (a) There is a reference to the accepted circumference of the Earth, as given in the *Khaṇḍakhadyaka* (Sachau's *Alberuni*, Vol. I, p. 312)

Multiply the difference in longitude (from Ujjayini) by the (mean) daily motion of a planet (in minutes) and divide by 4,800; apply the quotient taken as minutes negatively in places east of the meridian line of Ujjayini and positively in places lying west.¹

- (b) The rules for finding the *ahargana* as given in the *Khaṇḍakhadyaka* in I. 3-5 (Sachau's *Alberuni*, Vol. II, 46-47), to which Dr. Schram adds a valuable annotation, the constants being taken from the later Pauliṣa Tantra as known to Bhāṭṭotpala. This Pauliṣa astronomy is derived from Āryabhata I's *ardharātrika* system.²

- (c) A quotation from the *Uttara Khaṇḍakhadyaka* (Sachau's *Alberuni*, Vol. II, pp. 84-86) which Sengupta has given in his translation, Chapter X, pp. 148-152.

- (d) A quotation also probably from the *Uttara Khaṇḍakhadyaka* (Sachau's *Alberuni*, Vol. II, p. 87). These stanzas are found in the *Brāhmasphuṭasiddhānta*, XIV, 47-52, also quoted by Bhāṭṭotpala as occurring in the *Brahma Siddhānta* in his commentary on the *Bṛhat-Samhitā*, IV, 7. The manuscripts which Sengupta used did not show them as occurring in the *Uttara Khaṇḍakhadyaka*. These relate to the dimensions of the *nakṣatras* as seen, as distinguished from the same as calculated.

1. उज्जयिनी-याम्योत्तर-रेखायाः प्रागृणं धनं पश्चात् ।

देशान्तर भुक्तिवधात् ख खाष्टवेदैः कलायाप्तम् ॥

2. - *KK*, Pt. B. Misra's edition, p. 145.

- (e) Two quotations from the *Uttara Khaṇḍakhādyaka* relating to the celestial co-ordinates of Canopus and Sirius (Sachau's Alberuni, Vol. II, p. 91). Present manuscripts do not show these stanzas, which are probably the same as stanzas 35-36 and 40 of Chapter X of the *Brāhmasphuṭasiddhānta*.
- (f) Two quotations from the *Khaṇḍakhādyaka* proper as alleged by Alberuni (Sachau's Alberuni, Vol. II, p. 116). According to Āmarāja, the first is a couple of stanzas of which the author is Bhaṭṭotpala and not Brahmagupta. The second quotation cannot be traced. These relate to finding the possibility of an eclipse whether of the Sun or of the Moon.
- (g) Two quotations from the *Khaṇḍakhādyaka* proper as asserted by Alberuni (Sachau's Alberuni, Vol. II, p. 119). These relate to finding the Lords of the year and of the month. According to Āmarāja the rules in question were given by Bhaṭṭotpala and not by Brahmagupta. Pṛthūdaka in his commentary on the first chapter at its concluding portion says ;

"In this work the *Khaṇḍakhādyaka*, the teacher (Brahmagupta) has not given the rules for finding the Lords of the year and the month¹."

1. अथाऽत्र खण्डखाद्यके वर्षाधिपमासाधिपा नयनमात्राव्ययेण नाभिहितम् ।

Brahmagupta's Originality in the *Khaṇḍakhādyaka*

Sengupta in his Introduction to the Commentary of the *Khaṇḍakhādyaka* has discussed this point. We shall reproduce here some of the points mentioned by him.

Brahmagupta's *Khaṇḍakhādyaka*

(i) Brahmagupta does not accept the system of Āryabhaṭa but has simplified it in the *Khaṇḍakhādyaka* proper ; and here he has given the system which he thinks to be correct.

Uttar Khaṇḍa Khādyaka

(ii) In the *Uttara-Khaṇḍakhādyaka*, he has further corrected some of his results, given earlier in the *Khaṇḍakhādyaka* proper. In the proper *Khaṇḍakhādyaka*, Brahmagupta assigns to the longitude of the Sun's apogee the value 80° , whereas in the *Uttara* text he corrects it to 77° (UKK. 4) :

As the process of finding the apparent places of planets as given by Āryabhaṭa does not make them agree with observation, I shall, therefore, speak of this process. Of the Sun the apogee is at two signs and seventeen degrees ($2 \text{ signs } 17^\circ = 60 \text{ plus } 17 \text{ degrees} = 77^\circ$).¹

Compare this with the value given in the *Khaṇḍakhādyaka* proper (I.13)² :

The longitude of the Sun's apogee is 80° [KK.I,13] (The Sun's apogee is 80° or two signs plus 20 degrees) *inocco* means

1. न स्फुटमार्थ्यभटोक्तं स्पष्टीकरणं यतस्ततो बहये ।
भानुमती मन्दोच्चं राशिद्वयं राकाश्च सप्तदश ॥
2. भागाशीतिरिनोच्चं राशिनः पादोनकृत शरकृतोनाद् ।
भगणादि द्वित्रिरदैर्बसुनव यम नव गुणैः सकलम् ॥

UKK. IX 4

KK. I, 13

mandocca of the Sun). The value given in the *Pañcasiddhāntikā*, IX.7-8) is also the same.

Let us compare it with the present value. According to the astronomical constants as given in the *Conn. des Temps*., the longitude of the Sun's apogee in 499 A.D. (i.e. 1,400 years before 1900 A.D.) was

—77° 19'19.44" according to *Conn. des Temps*'
equation.

—76° 40'37.22" according to Newcomb's equation.

The mean of these two values is very nearly 77° as given by Brahmagupta in the *Uttara* text. Thus the value given by Brahmagupta is more correct than the value given by Āryabhaṭa. The *Āryabhaṭiya* gives the value 78° which is less correct.

Brahmagupta more correct than Āryabhaṭa

(iii) Brahmagupta detected that Āryabhaṭa had made the Moon's apogee quicker and nodes slower, than they really are. In both the cases, Brahmagupta made rather an over-correction. We shall give the extract from *Uttara-Khaṇḍakhadyaka* in this connection :

Multiply the *ahargana* by 110, increase the product by 511 and divide by 30, 31; subtract the result taken as revolutions, etc., from the mean Moon; the final result is the Moon's apogee.¹

Evidently Brahmagupta assumes that the anomalistic month=3031/110 days. This convergent to the anomalistic month was known to the author of the *Vasiṣṭha Siddhānta* as summarised in the *Pañcasiddhāntikā*² (II-2-6).

According to Brahmagupta, the length of the anomalistic month.

$$\begin{aligned}
 &= \frac{1582236450000 - 4320000000}{57753300000 - 488105858} \text{ days. (BrSpSi. I.15,16,18, and 20)} \\
 &= 27.55454641 \text{ days which is for 1900 A. D.} \\
 &= 27.5545502 \text{ days according to Radau.} \\
 &= 27.554602 \text{ according to the } \textit{Āryabhaṭiya}.
 \end{aligned}$$

1. यद्गुण्यत् खं रुद्रं गुण्यतां भवशरयुक्ताच्छशिनिखाग्निं हतात् ।
भगवतादि फलं शोध्यतः परमवन्द्याच्छशाङ्कोच्चम् ॥

Here also Brahmagupta is more accurate.

Again, the length of the sidereal period of the Moon's apogee

$$= \frac{1577918450000}{488105858} \text{ days} \\ = 3232.732048 \text{ days.}$$

Āryabhaṭa's value of the same is 3231.987844 days, and the modern value is 3232.3754 days. Hence Brahmagupta's result is by 0.3566 of a day out, while Āryabhaṭa's is by 0.3876 of a day in.

Further in the *Uttara-Khaṇḍakhādyaka* (IX.10) we have : Deduct 354½ from the *ahargana*, divide the remainder by 6792 ; subtract the quotient that is obtained in revolutions etc. from the circle : the result is the longitude of the ascending node.¹ (IX.10)

Here Brahmagupta gives the approximate period of the sidereal revolution of the Moon's node to be=6792 days. This according to his *Brāhmasphuṭasiddhānta*= $\frac{1577916450000}{232311168}$ days

= 6792.25396 days, which according to Lockyer would be 6793.39108 days and according to the *Khaṇḍakhādyaka* proper is 6794.75083 days. Hence Brahmagupta's attempt to correction makes the node quicker than it actually is.

Brahmagupta corrects Mars's Aphelion Point

(iv) Again Brahmagupta states that the longitude of Mars's aphelion should be increased by 17° and that of Jupiter by 10°. Evidently here too, Brahmagupta is more correct than Āryabhaṭa. The passage in the *Uttara Khaṇḍakhādyaka* is as follows in this connection :

Of Mars the apogee (the aphelion point) is to be increased by 17°, that of Jupiter by 10° ; from the *siḡhra* of Venus 74' are to be subtracted ; Saturn's equation of apsis should be decreased by its one-fifth ; the *siḡhra* equation of Mercury should be increased by

1. सार्द्धं कृतेषु गुणोनादहर्गणाद् दिनवमुनि-रसैर्भक्तात् ।

अभ्यसङ्ख्यादि लब्धं चक्रात् संशोध्य तत् पातः ॥

one-sixteenth.¹

This stanza says that in 499 A.D., Mars's aphelion point had a longitude of 127° ; of Jupiter the longitude of the aphelion was 170° . (KK.II. 6³)

According to Newcomb's rule, the longitude of the aphelion point of Mars in 499 A. D. works out to have been $= 128^{\circ}28'12''$. According to the *Conn. des. Temps'* rule, the same was $128^{\circ}27'51''$. Hence Brahmagupta's determination of Mars's aphelion is correct within $1^{\circ}30'$ and is therefore, quite satisfactory. According to the *Khaṇḍakhādyaka* proper it was 110° , and according to the *Āryabhaṭīya* 118° .

Of planets, beginning with Mars, the degrees of longitude of the apogees are respectively 11, 22, 16, 8 and 24, each multiplied by 10. (KK.II. 6)

Thus the longitudes of apogees of Mars $= 110$ (3 signs 20°); of Mercury $= 220$ (7 signs 10°); of Jupiter $= 160$ (5 signs 10°); of Venus $= 80$ (2 signs 20°) and of Saturn $= 240$ (8 signs). Compare these values with those given in the *Pañcasiddhāntikā* XVII. 2 (the *Sūrya-siddhānta*).

Again according to this stanza Jupiter's aphelion had a longitude of 170° in 499 A.D.

According to *Conn. des. Temps'* rule the same was $170^{\circ}25'$. Thus here too, Brahmagupta is very accurate. According to the *Khaṇḍakhādyaka* proper, Jupiter's aphelion had a longitude of 160° (KK. II.6) and according to the *Āryabhaṭīya*, the value was 180° .

Brahmagupta First to Use Second Differences

All these illustrations reproduced here very well establish the point that the great Indian astronomers from Āryabhaṭa I to Brahmagupta were aware of the methods of separating the two distinct planetary inequalities, viz., that of the apsis and of conjunction in the cases of the five 'star' planets (PSi. Introduction Lii). In the *Khaṇḍakhādyaka*, Brahmagupta having given the "sines" and the equations of the Sun and the Moon

1. सप्तदशांशैरधिकं भौमस्योच्चं गुरोर्द्वाराभिरंशैः ।

सितशीघ्रात् कृतमुनयो लिप्ताः शोध्याः शनैः फलं मान्यम् ॥

पञ्चांशोर्न शैब्यं षोडशभागाधिकं बुधस्य फलम् ॥

2. मन्दांशा दशगुणिता रुद्रा द्वियमाश्च षोडशाष्टजिनाः ।

—UKK. IX. 11

—KK. II. 6

at the interval of 15° of arc of the mean anomaly, in the *Uttara Khandakhadyaka* teaches, for the first time in the history of mathematics, the improved rules for interpolation by using the *second difference*. This very important feature I am reproducing here from the translation by Senagupta of the verse ¹ (UKK. 8):

Multiply the residual arc left after division by $900'$ (i.e. by 15°), by half the difference of the tabular difference passed over and that to be passed over and divide by $900'$ (i. e. 15°): by the result increase or decrease, as the case may be, half the sum of the same two tabular differences; the result which, whether less or greater than the tabular difference to be passed, is the true tabular difference to be passed over. (UKK. 8)

The rule given here applies to the case of all functions hitherto considered in the *Khandakhadyaka*, which are tabulated at the difference of 15° of arc of the argument. They are:

- (i) the tabular differences of the Sun's equation,
- (ii) the tabular differences of the Moon's equation.
- (iii) the tabular differences of the 'sines'.

Sengupta has illustrated the rule by an example belonging to the table of sines.

Illustration—To find the 'sine' of 57° .

Brahmagupta's table of sines in the *Khandakhadyaka* is as follows:

Thirty increased severally by nine, six and one; twenty-four, fifteen and five, are the tabular differences of sines at intervals of half-a-sign. For any arc, the 'sine' is the sum of the parts passed over, increased by the proportional part of the tabular difference to be passed over.² (KK.I.30; also III.6)

1. गतभोग्य खण्डकान्तरदलविकलवधात् शतैर्नवभिराप्या ।
तदशुतिदलं युतोर्न भोग्यादूनाधिकं भोग्यम् ॥

—UKK. IX. 8

2. त्रिंशत् सनवरसेन्दुजिन (तिथि) विषयागृह्णाद् चापानां ।
अर्द्धज्या खण्डानि ज्या भुक्तैर्व्य सभोग्यफलम् ॥

—KK. I. 30; also III. 6

This can be shown in the tabular form thus :

Arc	'Sine'	Tabular difference	Second difference
0°	0		
15°	39	39	
30°	75	36	—3
45°	106	31	—5
60°	130	24	—7
75°	145	15	—9
90°	150	5	—10

Now $57^\circ = 3420 \text{ minutes} = 900' \times 3 + 720'$. Thus three of the tabular differences are considered as passed over ; the last one being 31 and the one to be passed over is 24.

The true tabular difference by the rule, for arc 57° ,

$$= \frac{31+24}{2} - \frac{720}{900} \times \frac{31-24}{2}$$

Hence the 'sine' of 57°

$$= 39 + 36 + 31 + \frac{720}{900} \left[\frac{31+24}{2} - \frac{720}{900} \times \frac{31-24}{2} \right] \\ = 125.76$$

As worked out from the logarithm tables the same comes out to be 125.80.

Again 'sine' of 57° from Brahmagupta's formula

$$= 106 + \frac{720}{900} \times 24 + \frac{31-24}{2} \times \frac{720}{900} - \left[\frac{720}{900} \right] \times \frac{31-24}{2} \\ = 106 + \frac{720}{900} \times 24 + \frac{720}{900} \left[\frac{720}{900} - 1 \right] \times \frac{24-31}{2}$$

This in fact is the modern form the interpolation equation up to the term containing the second difference. Brahmagupta thus takes a decidedly improved step here and is undoubtedly the first man in the history of mathematics who has done this. One should also remember that in the case where the function is not tabulated at a constant interval, Brahmagupta's rule is remarkable.

Brahmagupta First to Introduce Sine Rule in Indian Plane Trigonometry

In this connection, we shall reproduce the following verse from the *Khaṇḍakhādyaka* :

Multiply the 'sine' of the (*Śighra*) anomaly by the 'sine' of the maximum *Śighra* equation and divide by the 'sine' of the corresponding *Śighra* equation, the result is the '*Śighra* hypotenuse' when the (*Śighra*) anomaly is half a circle, this *śighra* hypotenuse is equal to the radius diminished by the 'sine' of the maximum equation ; when the anomaly is equal to the whole circle, the same is equal to the radius increased by the same 'sine' of the maximum equation.¹

Let S, E and P be the positions of the Sun, the Earth and the

Fig. 4

planet, say Mars, respectively. Complete the parallelogram SEMP ; with M as centre and MP as radius, describe a circle. This circle is the epicycle of conjunction of Mars. Produce EM to cut this circle at K. The $\angle PMK = \angle S'SP$ (the point S' is on ES produced), the angle

gained by the Earth over Mars since the preceding conjunction. The $\angle PMK$ is called the *śighra* anomaly or anomaly of conjunction. We take $EM=360$, and $MP=234$. The $\angle PEM$, which is equal to $\angle PES$, the annual parallax of Mars, is called the *śighra* equation. The $\angle MPE$ is equal to the $\angle SEP$, the elongation. The $\angle PMK$ is given, and PM and ME are also given. Hence in the triangle MPE, we have

$$\begin{aligned} \tan \frac{1}{2}(P-E) &= \frac{EM-MP}{EM+MP} \tan \frac{1}{2} PMK \\ &= \frac{126}{594} \tan \frac{1}{2} PMK \end{aligned}$$

$$\therefore L \tan \frac{1}{2}(P-E) = \log \left[\frac{126}{594} \right] + L \tan \frac{1}{2} PMK$$

We have also $\frac{1}{2}(P+E) = \frac{1}{2} \angle PMK$

1. केन्द्रज्याऽन्यकलज्या गुणिता फलजीवया हताकर्णः ।

त्रिज्याऽन्य फलज्योना चक्राद्धे संयुता चक्रे ॥

$$\text{Now } \log \left[\frac{126}{594} \right] = 1.3265841.$$

The values of the $\angle PMK$ and the $\angle PEM$ and Brahmagupta's values as given in the verse¹ are presented below in a tabular form :

$\angle PMK =$	28°	60°	90°	121°	135°	148°	164°	173°
$\angle PEM =$	10°58'	23°1'	33°1'	39°56'	40°23'	37°31'	25°32'	12°35'
Brahmagupta's $\angle PEM =$	11°	23°	33°	40°	40°30'	37°30'	25°30'	12°30'

It will be seen that Brahmagupta gives the values of the equation within 1/8th of a degree. It seems inexplicable why such discrepancies should remain in Brahmagupta's calculations. It is probable that he wanted to state his equations to the nearest half a degree.

Now we shall take up the *Sighra* equations of Mars, and then revert to the Sine Rule. We have in the *Khanḍakhādyaka* :

Mars, by the degrees of *Sighra* anomaly (i.e. anomaly of conjunction) of 28 getting at the corresponding equation of 11° rises (heliacally) in the east ; by the next 32° gets 12° more of the equation ; by the next 30°, 10° more ; by the next 31°, 7°, more ; by next 14°, half a degree ; these are positive ; by the next 13°, negative 3° ; by the next 16° ; negative 12° after this he is retrograde ; by the next 9°, negative 13° ; by the next 7°, negative 12½°. After this the parts of the equations occur in the reverse order¹.

On the basis of this we have the following table of the *Sighra* equations for Mars ;

Degrees of anomaly of conjunction	Equation of conjunction	Phenomena
0°	0°	Motion direct.
28°	+11°	Rises in the east.

1. भौमोऽष्टयमै रुद्रान् मुक्त्वा पूर्वोदितोरदैरकां ।

Degrees of anomaly of conjunction	Equation of conjunction	Phenomena
60°	11+12=+23°	
90°	23+10=+33°	
121°	33+ 7=+40°	
135°	40+ ½=+40°30'	
148°	40°30'—3°=+37° 30'	
164°	37°30'—12°=+25°30'	Retrograde motion begins.
173°	25°30'—13°=+12°30'	
180°	12°30'—12°30'=0°0'	
187°	—12°30'	
196°	—25°30'	Direct motion begins.
212°	—37°30'	
225°	—40°30'	
239°	—40°	
270°	—33°	
300°	—23°	
332°	—11°	Sets in the west.
360°	0°	

Now we come back to our discussion on the verse VI.1.

The *Śighra* hypotenuse spoken of here is EP, when SP or EM is taken to be R; when $\angle PEM$ is a maximum, PM is its 'sine'.

It would be seen from the figure that

$$EP = \frac{R \sin PMK \times PM}{R \sin PEM}$$

This may again be written as

$$\frac{EP}{\sin PMK} = \frac{PM}{\sin PEM}$$

This is equivalent to the sine rule for a triangle in plane trigonometry. Brahmagupta is here seen to be the first person to give it in Indian mathematics. This expression reminds us of the famous relationship in respect to triangle ABC :

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C}$$

**Brahmagupta corrects
Dimensions of the Epicycle of Apsis**

Brahmagupta corrects the dimensions of the epicycles of apsis of the Sun and Moon by—1/42nd part and 1/48th parts respectively, The reference may be made to the following verse in the *Uttara Khanḍakhādyaka* :

The Sun's equations are to be made less by *dvikṛtāṁsonam* (1/42nd) and the Moon's equations, increased by *vasuvedabhāgayutam* (1/48th). Multiply the Sun's equation a planet's daily motion in minutes and divide by the number of minutes of a whole circle and this is called *Bhujāntara* correction and applied in the same way to the planet as the equation is applied to the Sun.¹

The Sun's epicycle of apsis has the dimension 14" in the *Khanḍakhādyaka* proper. With the correction introduced here, the value becomes $14^\circ \left[1 - \frac{1}{42} \right] = 13^\circ 40'$.

The correction to the Moon's equations would make the epicycle's dimension changed from 31° to $31^\circ \left[1 + \frac{1}{48} \right] = 31^\circ 38' 45''$.

Prthūdaka's commentary further corrects it to $31^\circ (1 + \frac{1}{52}) = 31^\circ 35'$.

Brahmagupta's correction to Saturn's epicycle of apsis is—1/5th part and that to the *Śighra* epicycle of Mercury 1/16th part as seen in the verse :

Of Mars the apogee (the aphelion point) is to be increased by 17°, that of Jupiter by 10°; from the *Śighra* of Venus 74' are to be subtracted; Saturn's equation of apsis should be decreased by its one-fifth and the *Śighra* equation of Mercury should be increased by one-sixteenth.²

In the *Khanḍakhādyaka* proper (II.6), we have been given the longitudes of the apogee of planets: Mars 11°, Mercury 22°, Jupiter 160°, Venus 80° and Saturn 240°. Now with these corrections introduced in the *Uttara Khanḍakhādyaka* in the above

1. द्विकृतांशोर्न रविफलमिन्दोर्वसुवेदभागयुतम् ।

अर्कफलमुक्तिधाताद् भगणकालान्तं सृजान्तरं रविवत् ॥

UKK. IX. 9

2. सप्तदशांशैरधिकं सौमस्योच्चं गुरोर्दशभिर्दशैः ।

सितशशिवात् कृतमुनयो लिप्ताः शोभ्याः शनैः फलं मान्यम् ।

पञ्चांशोर्न शैब्यं षोडशाभाः॥धिकं बुधस्य फलम् ॥

UKK. IX. 11

verse, the aphelion point of Mars in 499 A.D. had a longitude of $110 + 17 = 127^\circ$; of Jupiter $160 + 10 = 170^\circ$.

According to Newcomb's rule, the longitude of the aphelion point of Mars in 499 A.D. works out to have been $128^\circ 28' 12''$. The same according to *Conn. des Temps* rule would be $128^\circ 27' 51''$. Hence Brahmgupta's determination of Mars's aphelion is correct within $1^\circ 30'$, and may be, therefore, regarded as very satisfactory. According to the *Khaṇḍakhādyaka* proper this value was, as already said, 110° , while according to the *Āryabhaṭīya*, it was 118° .

The same may be said regarding Jupiter's aphelion. According to the *Khaṇḍakhādyaka* proper the value of its longitude is 160° , according to the *Āryabhaṭīya* it was 180° ; according to *Conn. des Temps*' rule, it would be in 499 A. D. $170^\circ 25'$, and the value given by Brahmagupta in the *Uttara Khaṇḍakhādyaka*, it is 170° .

We have thus shown by many illustrations the important corrections introduced by Brahmagupta in his *Khaṇḍakhādyaka* specially the *Uttara* part. Brahmagupta was highly original in his methods of calculations, accuracies and interpolations. He introduced new ideas in mathematics. He went much ahead Āryabhaṭa in many details. He so many times did not follow Āryabhaṭa in calculations. In the *Khaṇḍakhādyaka* proper, his treatment of parallax in the calculation of solar eclipses is different from that of Āryabhaṭa. The methods followed here are the same as propounded by him in the *Brāhmasphuṭasiddhānta*.¹

Senagupta is right when he says : As has already been remarked, these corrections and innovations in the *Uttara Khaṇḍakhādyaka* paved the way for the acceptance of his great work the *Brāhmasphuṭasiddhānta* as a standard work on astronomy by the western Indian school of astronomers. The directness of the treatment of topics, and the simplicity of calculations taught in the *Khaṇḍakhādyaka* made it very neat handbook for the beginner. These two works of Brahmagupta were perhaps the only astronomical works in circulation in western India when the Arabs conquered Sind early in the eighth century

(712 A.D.) and the new conquerers learnt Indian astronomy and mathematics from these works as has been observed by Sachau. Alberuni who came to India early in the 11th century of the Christian era, learnt Indian astronomy chiefly by studying the *Khaṇḍakhādyaka* and the *Bṛhat-Saṃhitā* of Varāhamihira, and both of them with the help of commentary of Bhaṭṭotpala.

CHAPTER VI

Indian Luni- Solar Astronomy

In this chapter, it is proposed to give an account of astronomical constants and the equations in Indian luni-solar astronomy and to present a comparative view of these quantities with the corresponding ones in Greek and modern Astronomy. This account has been reproduced from P. C. Sengupta's. Appendix I of the *Khaṇḍakhādya*. It has been shown that in many cases the Indian values of these constants are more accurate than the Greek values. and in Indian lunar astronomy the equations or inequalities discovered are the most startling.

Solar Astronomy

In solar astronomy the length of the year was determined by Āryabhaṭa¹ from the heliacal risings of some bright star at the intervals of 365 and 366 days.

(1) The year according to the Āryabhaṭīya

$$= \frac{1577917500}{4320000} \text{ days} = 365.2586805 \text{ days,}$$

$$= 365 \text{ da. 6 hrs. 12 mins. 29.64 secs.}$$

(2) The same

$$= \frac{1577917800}{4320000} \text{ days} = 365.25875 \text{ days.}$$

$$= 365 \text{ da. 6 hrs. 12 mins. 36 secs., according to the}$$

Khaṇḍakhādya, the *Sūryasiddhānta* of Varāha
and the modern *Sūryasiddhānta*.

(3) It is

$$= \frac{1577916450}{4320000} \text{ days} = 365.2584375 \text{ days,}$$

$$= 365 \text{ da. 6 hrs. 12 mins. 9 secs., according to the}$$

1, P. C. Sengupta, "Āryabhaṭa's Method of determining the Mean Motions of Planets," *Bulletin of the Calcutta Mathematical Society*. Vol. XII, No. 3.

Brahmasphuṭa Siddhānta of Brahmagupta.

Now the mean sidereal year

$$= 365 \text{ da. } 6 \text{ hrs. } 9 \text{ mins. } 9.3 \text{ secs. (Lockyer).}$$

The mean anomalistic year

$$= 365 \text{ da. } 6 \text{ hrs. } 13 \text{ mins. } 49.3 \text{ secs. (Lockyer).}$$

The mean tropical year

$$= 365 \text{ da. } 5 \text{ hrs. } 48 \text{ mins. } 46.054 \text{ secs. (Lockyer).}$$

Though we take that Indian year was designed to be the sidereal year, it approached most closely the anomalistic year; and its excess over the sidereal year was about 3 minutes. From this consideration it appears that the Indian astronomers were justified in taking the Sun's apogee to be fixed.

Against the error of +3 min. in the Indian sidereal year, we may point out that—

(1) The Hipparchus-Ptolemy tropical year

$$= 365 \text{ da. } 14' 48'' \text{ in sexagesimal units.}^1$$

$$= 365 \text{ da. } 5 \text{ hrs. } 55 \text{ min. } 12 \text{ secs., which has an error of about } +6 \text{ min.}$$

(2) Meton's sidereal year

$$= \left[365 + \frac{1}{4} + \frac{1}{76} \right] \text{ days}^2$$

$$= 365 \text{ da. } 6 \text{ hrs. } 18 \text{ min. } 57 \text{ secs., which has an error of } +9 \text{ min. } 48 \text{ secs. nearly.}$$

(3) The Babylonian sidereal-year was $4\frac{1}{2}$ min. too long.³

Thus the Indian value of it is closer to the true value.

Again in 150 A.D. the longitude of the Sun's apogee according to the *Conn. des Temps* was

$$= 101^\circ 13' 15''.17 - 6189''.03 \left[\frac{1900-150}{100} \right]$$

$$= 1''.63 \times \left[\frac{1900-150}{100} \right]^2$$

$$= 71^\circ 16' 26''.37$$

while Ptolemy states it to be $65^\circ 30'$ which was wrong by $-5^\circ 36' 27''$:

1. *Syntaxis*, Karl Manitius's edition, Vol. I. p. 146.

2. *Ibid*, p. 145.

3. *Encyclopaedia Britannica*, History of Astronomy.

4. *Syntaxis*, Vol. I. p. 148. The *Romaka Siddhānta* of the *Pañca-siddhāntikā*, VIII. 2, indicates the Sun's apogee to be at longitude of 75° ; this was perhaps a correction made by Lāṭādeva to the Greek constant.

In 500 A. D (Āryabhaṭa's time) the longitude of the Sun's apogee by the same rule works out to be $=77^{\circ}19'19.44''$.

Āryabhaṭa states this to be 78° in the *Āryabhaṭīya*, Brahmagupta in the *Uttarādhyaīya* of the *Khaṇḍakhādya* states the same to be 77° , while the *Khaṇḍakhādya* gives it as $=80^{\circ}$. Hence the Indian findings of the longitude of the Sun's apogee were more accurate.

Again as to the Sun's equations of the centre we find that the *Āryabhaṭīya* states the periphery of the Sun's epicycle to be $13^{\circ}30'$. The *Khaṇḍakhādya* gives it as 14° ; while according to the Indian form, Ptolemy's value of the same is 15° . Hence according to these writers, the Sun's equations at 90° of the mean anomaly are :—

According to the *Āryabhaṭīya* $=2^{\circ}8'54''$.

„ „ *Khaṇḍakhādya* $=2^{\circ}1'40''$.

„ „ Brahmagupta $=2^{\circ}7'20''$.

„ „ Ptolemy $=2^{\circ}23'3''$.

The modern value $=1^{\circ}55'97''$.

Thus the Indian equations of the Sun are in general by more correct than the Greek ones. The Indian constants in solar astronomy are thus, generally, more accurate than the Greek ones. We now turn to the Indian Lunar astronomy.

Lunar Astronomy

Before discussing the constants in Indian lunar astronomy it is necessary to state something as to the time when the Moon was observed by our ancient astronomers and the astronomers from Āryabhaṭa I (499 A.D. to Pṛthūdaka Svāmī (864 A.D.). The months were reckoned from the first visibility of the crescent at the time of the *Mahābhārata* (1400 B. C.). We have a passage in the *Bhīṣmaparva* where Vyāsa speaks of the evil omens on the eve of the Kurukṣetra war thus—

चन्द्रसूर्यबुधौ ग्रस्तावेकामासौ त्रयोदशीम् ।

“That the Moon and the Sun have been both eclipsed on the 13th days of the light and dark halves of the same month.”

The eclipses could not take place on the 13th days of the month unless the months were reckoned from the first visibility of the crescent. This was the custom in Babylonia and it has still survived in the Mahomedan world. Even in the *Pañca siddhantikā* of Varāhamihira (540 A. D.), there is a special

chapter on शशि-दर्शनम् or the first visibility of the crescent. It is thus clear that the practice was to observe the Moon when very near the Sun.

Again Āryabhaṭa says that 'खीन्दुयोगात् प्रसाधितश्चेन्दुः', "the Moon was determined from her conjunctions with the Sun." The Moon was observed by him at the time of solar eclipses, or at the time of the first visibility of the crescent.

Even up to the time of Pṛthudaka, the accuracy in lunar astronomy was chiefly aimed at the time of eclipses. Thus in his commentary on the *Khaṇḍakhādya*. IV, he makes the following introductory remarks :—

"All knowledge relating to (luni-solar) astronomy is desired by the wise (or cultured) specially for knowing the right instants of opposition or conjunction ; these instants are, however, not visible to the eye. Of other things such as *tithis*, *nakṣatras* and *Karanas*, as the planets, the Sun and the Moon, are not clearly observed, their beginnings and ends are not visible. Men see the agreement between calculation and observation at the times of solar and lunar eclipses. Hence the word of the astronomers is esteemed amongst men even in respect to such things as *tithis*, etc."¹

Thus the chief aim of the ancient Indian astronomers was to calculate the eclipses accurately and the Moon was observed chiefly at lunar or solar eclipses, though the time for observation related also to the finding of the first visibility of the crescent. This latter phenomena did not perhaps lead them to directly observing the Moon's position at such times by using instruments.

Moon's Mean Motion

The practice of observing the Moon at the time of the eclipses alone led to the determination of the synodic month with the following results :—

(i) Mean synodic month according to the *Āryabhaṭīya*

$$= \frac{1577917500}{57753336 - 4320000} \text{ days,}$$

$$= 29.530582 \text{ days.}$$

1. बाहुल्येन पर्वज्ञानार्थं सकलं ज्ञानमिष्यते शिष्टैः । तेषां च पर्वार्थां दर्शनं नास्ति । अन्येषामपि तिथिनिश्चयकरण्यानां तस्मात् तेषां शशिभास्करयोरव्यन्तिर्यस्मात् । शशिभास्कर-ग्रहययोरङ्गं गणितैक्यं लोकः पश्यति । तस्मात् तिथ्यादिष्वप्यर्थेषु देवहं वाक्यं लोके आद्रियते ।

(ii) The same according to the *Khaṇḍakhādya*
=29.5305874 days.

(iii) The same according to the *Brāhma-sphuṭa-siddhānta*
=29.530582 days.

(iv) The same according to Ptolemy=29 da. 31' 50" 8" 20"
in sexagesimal units=29.5305927 days

The modern value according to Newcomb and Radau
=29.5305881 days.

Hence the *Khaṇḍakhādya* mean length appears to be the closest approximation.

The mean sidereal month must have been deduced from the mean synodic month and the year adopted. Hence no comparison need be made of this element here.

We will now consider the sidereal periods, the nodes and the apogee of the Moon. These are shown below :-

According to	Sid. Per. of Moon's Apogee	Sid. per. of the Ascending Node
<i>Āryabhaṭīya</i>	3231.987079 da.	6794.749511 da.
<i>Khaṇḍakhādya</i>	3231.987844 da.	6794.750834 da.
<i>Brāhma-sphuṭa - Siddhānta</i>	3232.73411 da.	6792.25396 da.
Ptolemy	3232.617656 da.	6796.45571 da.
Modern values (Lockyer)	3232.37543 da.	6793.39108 da.

Here also the Indian values show a closer approximation to the true values, Brahmagupta's figures representing the nearest approach.

Other Constants

So far the Indian values of the constants have been more accurate than the Greek ones ; but as to the inclination of the Moon's orbit the Greek value is more accurate than the Indian value.

Inclination of the lunar orbit

Indian value=4°30'.

Greek value= $5^{\circ}0'$.

Modern mean value= $5^{\circ}8'43''.427$ (Brown)

This discrepancy confirms the conclusion, that the observation of the Moon was restricted to the time when she was near a node, either at solar or lunar eclipses, where a small error of observation magnified itself into about half a degree.

We now turn to the parallaxes of the Sun and the Moon :-

	Sun's Mean Hor. Parallax	Moon's mean Hor. Parallax
<i>Āryabhaṭīya</i>	3'55".62	52'30"
<i>Kaṇḍakhādyaka</i>	3'56"5.	52'42".3
Ptolemy	2'51"	53'34"
Modern values	0'8".806	57'2".79

As to the Sun's horizontal parallax, the ancients were of course totally wrong, but in respect to that of the Moon their values were fairly approximate.

We next consider the angular semi-diameters of the Sun and the Moon. These are :-

	Moon's Mean Semi-diameter	Sun's Mean Semidiameter
<i>Āryabhaṭīya</i>	15'45"	16'29".4
<i>Kaṇḍakhādyaka</i> (<i>Brāhma-sphuṭa-siddhānta</i>)	16'0".22	16'15"
Ptolemy	17'40"	15'40"
Modern values	15'33".60	16'1".8

Here also the Indian values are more accurate than the Greek values.

Moon's Equations. The First Equation.

It remains now to consider the Moon's equations in ancient Indian astronomy. As has been pointed out before, obser-

variation was up to the time of Brahmagupta, restricted to the time of eclipses perhaps also of syzygies.

The modern form of the Moon's equations is

$$= 377' \sin (nt-a) + 13' \sin 2(nt-a) + \dots\dots\dots$$

$$+ 76' \sin [2(nt-\theta) - (nt-a)] + 40' \sin 2(nt-\theta) \dots\dots\dots^1$$

where nt = mean longitude of the Moon, a the longitude of the perigee, θ = longitude of the Sun.

Here the first two terms, viz., $377' \sin (nt-a) + 13' \sin 2(nt-a)$, are due to elliptic motion about the Earth in one focus; the term $76' \sin [2(nt-\theta) - (nt-a)]$ is known as the evection term and the expression for the equation of centre becomes $= 301' \sin (nt-a) + 13' \sin 2(nt-a) + \dots\dots\dots + 152' \sin (nt-\theta) \cos (\theta-a) + 40' \sin 2(nt-\theta)$.

Now at syzygies and eclipses $\sin (nt-\theta)$ and $\sin 2(nt-\theta)$ will very nearly vanish. Hence according to modern astronomy at the syzygies and eclipses, the chief term of the Moon's equation $= 301' \sin (nt-a)$.

This according to the *Āryabhaṭīya*

$$= 300' 15'' \sin (nt-a)$$

“ “

Khaṇḍakhādyaka

$$= 296' \sin (nt-a)$$

“ “

Uttara Khaṇḍakhādyaka

$$= 301' 7'' \sin (nt-a)$$

“ “

Brāhmasphuṭasiddhānta

$$= 293' 31'' \sin (nt-a)$$

“ “

Greek astronomy

$$= 300' 15'' \sin (nt-a)$$

very nearly.

Hence both the Greek and the ancient Indian astronomers were very near the true value of the Moon's equation at the syzygies and eclipses. Godfray in his *Lunar Theory*, page 107, observes, “the hypothesis of an excentric, whose apse has a progressive motion as conceived by Hipparchus served to calculate with considerable accuracy the circumstances of eclipses; and observations of eclipses, requiring no instruments, were then the only ones which could be made with sufficient exactness to test

1. The accurate values of the coefficients appear to be $377' 19''.06$, $12' 57''.11$, $76' 26''$ and $39' 30''$.

the truth or fallacy of the supposition." We next consider the second inequality of the Moon.

Moon's Second Inequality or Equation

In ancient times it was Ptolemy who first really found a second inequality of the Moon. According to Godfray (*Lunar Theory*, p. 107) "by dint of careful comparison of observations he (Ptolemy) found that the value of this second inequality in quadrature was always proportional to that of the first in the same place, and was additive or subtractive according as the first was so; and thus, when the first inequality was at its maximum or $5^{\circ}1'$, the second increased it to $7^{\circ}40'$ which was the case when the apse line happened to be in syzygy at the same time."

It is well known that though Ptolemy discovered the second inequality in the Moon's motion he was not able to ascertain its true nature. His corrections in this case are true when at the quadrature the Moon's apse line passes through the Sun or it is at right angles to the line joining the Earth and the Sun.¹ In the general case his construction does not lead to the elegant form of the evection term as we know it now, nor does it lead to the nice form in which it was given by later Indian astronomers from the time of Mañjula (or Muñjala, 854 Śaka era = 932 A.D.).

As has already been pointed out, the early Indian astronomers from Āryabhaṭa to Brahmagupta aimed at accuracy in lunar calculation only for the eclipses and syzygies, and did not interest themselves about the Moon's longitude at the quadratures. Hence this second inequality is absent in the works of these makers of Indian astronomy, as also in the Pre-Ptolemaic Greek astronomy. This points to the conclusion that in both the earlier Indian and Greek systems of astronomy, the modes of observation of the Moon were copied from an earlier system of astronomy whether Babylonian or Chaldean. Even in the *Romaka Siddhānta* of the *Pañcasiddhāntikā*, there is no mention of evection.² Thus inspite of the transmission of a vague system of Greek astronomy, Indian astronomy as developed by Āryabhaṭa and Brahmagupta must be regarded as independent and

1. Godfray's *Lunar Theory*, pp. 108-110.

2. Vide the Summary in P.C. Sengupta's paper, "Āryabhaṭa the Father of Indian Epicyclic Astronomy." *Journal of the Department of letters*, vol. XVIII, Calcutta University Press.

original not only from this but also from other considerations. It sought to correct the constants as were obtained from the Babylonian and the Greek systems as has in some cases been shown already.

Mañjula's Second Equation of the Moon (932 A.D.)

We now take up in detail Mañjula's second equation of Moon. It is, however, necessary to say something about his first inequality.

This is given in the form

$$\frac{-488 \sin (nt-a')}{96 + \frac{488}{120} \cos (nt-a')} \text{ degrees.}$$

where nt stands for the Moon's mean longitude, a' —that of the apogee.

Hence when $nt-a'=90^\circ$, the equation = $\frac{488}{96} = 5^\circ 4' = 304'$ showing an excess of $4'$ over the modern value.

It is further necessary to modify the expression for the Moon's modern form of the equation by changing a to $180^\circ + a$, as in ancient Indian astronomy anomaly is measured not from the perigee but from the apogee.

The modified form is

$$\begin{aligned} &= -301' \sin (nt-a) + 13 \sin 2(nt-a) \dots \\ &- 152' \sin (nt-\theta) \cos (\theta-a) + 40' \sin 2(nt-\theta) + \dots \end{aligned}$$

Mañjula's lines giving the second equation are—

The (mean) daily motion of the Moon diminished by 11° and multiplied by the "cosine" of the longitude of the Sun diminished by that of the Moon's apogee is the multiplier of the "sine" and the "cosine" of the longitude of the Moon diminished by that of the Sun, divided severally by 1 and 5. The results taken as minutes are to be applied negatively and positively to the Moon and to her daily motion if the quantities multiplied together are of opposite signs and in the reverse order if they are of the same sign.¹

1. इन्द्रचोनाककोटिष्ठा गत्यंशा विभवा विधोः ।
गुणो व्यक्तेन्दोः कोट्योरूपं पञ्चाप्तयोः क्रमात् ॥
फले शशाङ्क-तदशत्वोर्लिप्ताथे स्वर्णयोर्वधे ।
ऋणं चन्द्रे धनं मुक्तौ स्वर्णं सान्य वधेऽन्यथा ॥

As to the positive or negative character of the "sine" and the "cosine" he gives the rule:—

The mean planet diminished by its *ucca*, the apogee, aphelion or the Śighra, is called *Kendra* or mean anomaly; its "sine" from above six signs (180°) arises from half circles and are respectively positive or negative, and its "cosine" in different quadrants are respectively positive, negative, negative, and positive.¹

The convention followed is that the "sine" is negative from 0° to 180° and positive from 180° to 360° of the arc and that the cosine is positive between 0° and 90°, negative between 90° and 270° and positive between 270° and 360°.

We may now symbolically express Mañjula's second inequality thus:—

$-(13^{\circ} 11' 35'' - 11'') \times 8^p 8' \cos(\theta - \alpha) \times 8^p 8' \sin(D - \theta)$ where D stands for the Moon as corrected by the 1st equation; we leave out the correction to the Moon's daily motion as given in the stanzas quoted above.

The moon's new equation comes out to be

$$= -143'58'' \cos(\theta - \alpha) \sin(D - \theta).$$

This, it will be seen, is exactly the modern form of the evection as combined with a part of the equation of apsis shown before. The difference in the main is that Mañjula's constant is 144', a quantity less by 8'. *In form the equation is most perfect, it is far superior to Ptolemy's, it is above all praise.* It is from this inequality, we trust, that Mañjula should have an abiding place in the history of astronomy. The next writer who gives the second equation is Śripati (1028 A.D.).

Śripati's Second Inequality of the Moon

The following stanzas from Śripati's *Siddhānta Śekhara*, it is said, were communicated to Sengupta by Pandit Babua Misra. Though they are probably not very correct still the general meaning is clear. They carry the following sense:

"From the Moon's apogee subtract 90°, diminish the Sun by the remainder left; take the "sine" of the

1. ग्रहः स्वोच्चोन्नितः केन्द्रं षड्द्व्योद्वेजो भुजः ।

धनार्थः पदशः कोटिधैनर्यं धनात्मिका ॥

result; multiply it by 160' and divide by the radius; the result is called *caraphala*. Put it down in another place, multiply it by *sara* (i.e., $R \text{ vers } (D-\alpha)$ or versed sine of the Moon's distance from the apogee) and divide by the difference between the Moon's distance (hypotenuse) and the radius; the result is called *paramaphala* (*cara*) *phala*, which is to be considered positive or negative according as the hypotenuse put down in another place is less or greater than the radius. Multiply the "sine" of the Moon which has been diminished by the apparent Sun, by the apparent *paramaphala* and divide by the radius; the final result is to be called *caraphala* to be applied to Moon negatively or positively as the Moon minus the Sun and the Sun minus the Moon's apogee (diminished by 90°) be of opposite signs; if these latter quantities be of the same signs, the new equation should be applied in the inverse order by those who want to make the calculation of the apparent Moon agree with observation.¹

Symbolically :—

$$\frac{160' R \sin[\theta - (\alpha - 90^\circ)]}{R} = \text{caraphala}$$

$$\mp \frac{160' R \sin[\theta - (\alpha - 90^\circ)]}{R} \times \frac{R \text{ vers } (D - \alpha)}{H - R}$$

$$= \text{paramaphala, according as } H > \text{ or } < R$$

The new equation

$$= \mp \frac{R \sin (D - \theta)}{R} \times \text{paramaphala}$$

1. त्रिभविरहितचन्द्रोच्चो नभास्वद्भुजज्या ।

$$\begin{aligned}
&= \mp \frac{160' R \sin[\theta - (a - 90^\circ)] R \text{ vers } (D - a) \times R \sin(D - \theta)}{R(H - R) \times R} \\
&= \mp \frac{160' R \cos(\theta - a) \times R \sin(D - \theta)}{R \times R} \times \frac{R \text{ vers } (D - a)^1}{H - R}
\end{aligned}$$

This equation is a slightly modified one but practically the same in form as that of Mañjula, except that the constant here is 160', greater than his by 16'. The constant is 160' also in Candrasekhara's form as we shall see later on. We next consider the Moon's inequalities as given by Bhāskara II in his *Bijopanaya*,* a special work on these inequalities composed in the Saka year 1074 (=1152 A.D.) two years after he had composed the *Siddhānta Śiromaṇi*.

Bhāskara II on Moon's Inequalities

His preliminary statement runs thus.—

112' positive or negative representing the maximum difference, have been found by me in the daily observed Moon (as calculated and as observed) at that point of the ecliptic where the arc from the *kadamba* (i.e., its pole) passing through the zenith cuts it.¹

Thus for observing the Moon he selected the nonagesimal as the suitable point where the uncertainty about her parallax is zero, and found $\mp 112'$ of arc to be the maximum difference between her calculated and observed places.

Mallabhaṭṭa, perhaps a contemporary of Bhāskara II, ascribed this difference to a supposed *Sighrocca* of the Moon. Bhāskara in stanzas 9-13, refutes the existence of the *Sighra* in the case of the Moon, the substance of his argument begins (i) that it is against the teaching of the *Sūrya-siddhānta* and other accepted authorities, (ii) that there is no variation of the apparent angular diameter of the Moon corresponding to this alleged *Sighra*, and (iii) that planets having a *Sighra* have retrograde motion which is never the case with the Moon.

*There is some uncertainty, about this new fraction introduced by Śripati.

1. लिप्ता विधोरकं महीमिता मे हग्गोचराः प्रत्यहमीक्षितस्य ।
कदम्ब गोलगत-सूत्रपाते क्रान्तौ धनर्यात्वजुषो समध्यात् ॥

The reasons for his new equations are stated as follows:—

When the Moon is situated at a quadrant ahead of the apogee and with the Sun at half a quadrant ahead of her, the maximum discrepancy (of 112') is seen in the negative character.

When the Moon is situated at three quadrants ahead of the apogee and with the Sun at half a quadrant behind her, the maximum discrepancy (of 112') is seen in the positive character.

When the eclipses of the Sun and the Moon take place at the apogee or the perigee of the Moon, the Moon as corrected by the equation of apsis is seen to be without any new correction called *bija*.

When the eclipses of the Sun and the Moon take place at the ends of the odd quadrants of the Moon's anomaly (measured from the apogee), the discrepancy is seen to be less by 34'.

When the Moon is at the apogee, whether the Sun be ahead or behind her by half a quadrant, the discrepancy amounts to be 34'.

The same discrepancy of 34' is observed when the Moon is at the perigee and the Sun is ahead or behind her by the same distance.

Thus by analysis and synthesis, and by repeated observations, this variable correction has been devised by me; let it be seriously considered by the learned.¹

Bhāskara here speaks of six cases and we consider them one after another:—

The Moon's equations as modified to suit *siddhāntas* are given by

$$-301' \sin (nt - a) + 13' \sin 2(nt - a) \dots$$

$$-152' \sin (nt - \theta) \cos (\theta - a) - 40' \sin 2(nt - \theta) + \dots$$

According to Bhāskara's *Siddhānta - siromani*, the Moon's equation of apsis

$$= -\frac{31^\circ 36'}{360^\circ} \times 3438' \sin (nt - a)$$

$$= -301' 46''.8 \sin (nt - a),$$

this agrees well with the corresponding term of the modern equation. As Bhaskara takes in all the six cases, $nt-a=90^\circ$, 270° , 0° or 180° , the second term of the equation of apsis vanishes.

Case I.

$$nt-a=90^\circ, nt-\theta=-45^\circ, \theta-a=135^\circ;$$

Here the total equation of the Moon

$$=-301'-(76'+40')=-301'-116'.$$

This fairly agrees with Bhāskara's observation, the difference being only of $4'$.

Case II.

$$nt-a=270^\circ, nt-\theta=45^\circ, \theta-a=225^\circ;$$

the total equation of the Moon

$$=301'+76'+40'=301'+116'.$$

This also agrees with Bhāskara's observation.

Case III.

$nt-a=0^\circ$ or 180° , $nt-\theta=0^\circ$ or 180° , $\theta-a=0^\circ$ or 180° , the total equation $=0'$, this also agrees with Bhaskara's observation.

Case IV,

$$nt-a=90^\circ \text{ or } 270^\circ, nt-\theta=0^\circ \text{ or } 180^\circ, \theta-a=90^\circ \text{ or } 270^\circ.$$

एवं व्यासात् समासाच्च पौनःपुन्येन वैयनात् ॥

चरबीजमिदं कल्पं रुषा सद्भिः समीक्ष्यताम् ॥ 25 ॥

the total equation = $\mp 301'$. This does not agree with Bhāskara's statement that the total equation
 $= \mp (301' \pm 78')$.

Case V.

$$nt - a = 0, nt - \theta = \pm 45^\circ, \theta - a = \pm 45^\circ,$$

the total equation

$$= 0' - 76' + 40' = -36' \text{ or } 0' + 76' - 40' = +36'.$$

This fairly agrees with Bhāskara's observation.

Case VI.

$$nt - a = 180^\circ, nt - \theta = \pm 45^\circ, \theta - a = 180^\circ \mp 45^\circ$$

the total equation

$$= 0' + 76' + 40' = 0' + 116', \text{ or } 0 - 76 + 40 = 0' - 36'.$$

This does not agree with Bhāskara's statement.

Bhāskara then states his first system of 24 equations corresponding to 24 sines in a quadrant to be 6', 13', 21', 27', 33', 39', 45', 51', 56', 61', 65', 68', 70', 72', 74', 75', 75', 76', 76', 77', 77', 78', 78', 78'.¹

These equations, he says—"are negatively added to the equation of apsis when that is negative and positively added to the same when that is positive"². In other words his new equations are complements of the equation of apsis, the two together being represented by

$$-301' 46'' \cdot 8 \sin (nt - a) - 78' \sin (nt - a)$$

$$\text{i.e., by } -379' 46'' \cdot 8 \sin (nt - a).$$

Hence next states his second set of equations depending on $\theta - D$, to be 6', 9', 13', 17', 22', 24', 27', 30', 32', 33', 34', 34', 34', 33', 31', 29', 26', 24', 20', 16', 11', 8', 3', 0'³ and says :

"These minutes are negative in the odd quadrants of the argument and are positive in other quadrants."⁴

When the value of the argument is 15°, the equation is 17',

"	"	"	45°	"	34'
"	"	"	90°	"	0'

1. *Bijopanaya*, 26-28.

2. "फलं ऋणे ऋणं ।

धने धनं मन्दफलेन द्युतम् ॥ 28 ॥

3. *Bijopanaya*, 29-32.

4. पताः कला श्रोजपदे ऋणं स्युर्धनं तदन्यत्र भवन्ति भूयः ।

$$\begin{aligned}\text{Hence the new equation} &= -34' \sin 2(\theta - D), \\ &= 34' \sin 2(D - \theta).\end{aligned}$$

Here the symbol D stands for the Moon as corrected by the ancient Indian equation of apsis and its complement as given by Bhāskara. It is readily seen that Bhāskara is the first of all the Indian astronomers to detect the equation known as "Variation" His constant, $34'$, is less than the modern value by about $6'$, and cannot be considered as a serious error.

We now see that the sum-total of the Moon's equation as given by Bhāskara

$$= -379' 46''.8 \sin(nt - \alpha) + 34' \sin 2(D - \theta),$$

the evection term being totally absent. This is a serious defect, and Bhāskara's new equations would make the Moon generally more incorrect at the syzygies and eclipses than what the ancient Indian equation of apsis would do.

Perhaps late in life when he was 69 years old in 1105 of Śaka era (=1183 A.D.) he discovered the inapplicability of his new equations at the times of eclipses and in his *Karaṇa-kuttahala* he altogether omitted these new equations which he had given in his *Bijopanaya*.

As to Bhāskara's second inequality which is really the complement of the equation of apsis without the evection term, it is far inferior to that of Mañjula and of Śrīpati; as we have seen their form of the second inequality combines the complement of the equation of apsis and evection in the mathematically correct form. For the discovery of such a form of the equation as of these authors, very patient, careful and frequent observation must have been coupled with very careful and nice comparison of observed facts.

As to "variation" it was first discovered by Abul-Wefa in 976 A.D.¹ which was quite forgotten when Tycho-Brahe re-discovered it in 1580 A.D. Hence Bhāskara in 1152 A.D., re-discovered it in India four centuries before Tycho.

Candraśekhara of Orissa on the Moon's Inequalities

In connection with lunar inequalities it is nesefsary here to record what were the equations discovered or verified by M.M. Candraśekhara Siṃha of Orissā in the later half of the last century. He was educated in the orthodox Sanskrit fashion

1. Godfray's *Lunar Theory*, p. 114.

and had no acquaintance with English education. His work *Siddhānta-darpaṇa* was edited by Prof. Jageschandra Ray, late of the Cuttack College, in 1899.¹ Candrasekhara in his work gives four equations of the Moon which are :-

- (1) The equation of apsis.
- (2) The Tungānta equation or the complement of the equation of apsis in combination with evection.
- (3) The fortnightly equation or variation.
- (4) The Digamśa equation or the annual equation (i. e., $\frac{1}{12}$ of the Sun's equation).
- (5) The first equation is of the form

$$\begin{aligned}
 &= \frac{[31^\circ 30' - 30' \cos (nt - a)] 3438 \times \sin (nt - a)}{360^\circ} \\
 &= -300' 49''.5 \sin (nt - a) + 4' 46''.5 \sin (nt - a) \cos (nt - a) \\
 &= -300' 49''.5 (\sin nt - a) + 2' 23''.25 \sin 2 (nt - a)
 \end{aligned}$$

It is seen that Candrasekhara wanted to correct the equation of apsis to the second order of small quantities as in all the Indian authors from Brahmagupta but Candrasekhara's form is correct though his constant is wrong.

- (2) His second equation is of the form

$$\begin{aligned}
 &\frac{160' \times 3438 \sin[\alpha - (\theta + 90^\circ)]}{3438} \times \frac{3438 \sin(D - \theta)}{3438} \\
 &\times \frac{\text{Moon's appt. daily motion}^2}{\text{Moon's mean motion}}, \\
 &= -160' \cos (\theta - \alpha) \sin (D - \theta) \\
 &\times \frac{\text{Moon's appt. daily motion}}{\text{Moon's daily mean motion}}
 \end{aligned}$$

Here the constant is the same as that of Śrīpati discussed before. The symbol means the Moon as corrected by the equation of apsis. It is readily seen that the constant of the first term of the equation of apsis is increased by 80'. and that the constant of evection is taken at 80'. In both the cases the error is about +4'.

- (3) Candrasekhara's third equation or Variation

$$= \frac{3438' \sin 2(D' - \theta)}{90} = 38' 12'' \sin 2(D' - \theta),^3$$

1. *Siddhānta-darpaṇa*, V, 100-114.
 2. *Ibid*, VI, 7-9
 3. *Siddhānta-darpaṇa* VI. 11-12.

where D' means the Moon as corrected by the 1st and the 2nd equations. Here the constant is wrong by $-1' 18''$.

(4) His fourth equation or the annual equation
 $= \pm \frac{1}{10}$ of the Sun's equation of apsis,¹

$= \pm \frac{1}{10} \times \frac{12 \times 3438}{360} \sin$ (Sun's distance from the apogee).

$= \pm 11' 27''.6 \sin$ (Sun's distance from the apogee).

The modern value of the constant is $11' 10''$. Tycho found it to be $4' 30''$. Horrocks' (1639) co-efficient was $11' 51''$.

As Candrasekhara was aware of Bhāskara's *Bijopanaya*, as also of the work of Śrīpati, his merit here lies in the discovery of the annual equation, and correction to the constant of variation.

Thus we have seen that so far as the luni-solar astronomy is concerned Indian astronomy is independent of Greek astronomy in respect of astronomical constants, that Indian astronomy is generally more accurate than Greek astronomy and that Indian astronomers were not mere "calculators"². There were observers who verified and corrected the old astronomical constants as they came down from Āryabhaṭa and Brahmagupta, who also found independently all the principal equations of the Moon.

CHAPTER VII

Greek and Hindu Methods in Spherical Astronomy

Here we shall reproduce from Sengupta's paper a comparative account of the Greek and ancient Indian methods in Spherical Astronomy and to bring out the independence of the Indian Astronomers on this subject. The views on this subject would necessarily differ from those of many European scholars such as Colebrooke and Bentley (early 19th century) to Kaye (early 20th century). Kaye wrote as follows in the *Journal of Asiatic Society of Bengal* 1919, No. 3.

The methods by which (the rules) were obtained are buried in obscurity. Braunmühl¹ has stated "that the Indians were the first to utilise the method of projection in the Analemma of Ptolemy." It is intended to present the Hindu methods as clearly as possible and to show that Braunmühl has not done sufficient justice to the Indian astronomers.

As to Kaye, we shall show that his remark quoted above is due to the fact that he had to rely mostly on the English translation of the *Sūryasiddhanta* of Burgess, and perhaps he had no access to the works of Bhāskara II (1150 A.D.), who was the first to explain the ancient Indian methods clearly.

Greek and Hindu Methods in Spherical Astronomy

Of the Greek methods in Spherical Astronomy, the history begins with elementary principles only from Euclid (300 B.C.). Even in Theodosius' *Sphaerica*² (about 153 B. C.) "there is nothing that can be called trigonometrical." Heath again says,

1. Heath, *Greek Mathematics*, Vol. II, p. 291. Braunmühl, *Geschichte der Trigonometrie*, pp. 38-42.
2. Heath, *Greek Mathematics*, Vol. II, p. 250.

"the early spheric did not deal with the geometry of the sphere as such, still less did it contain anything of the nature of the spherical trigonometry. (This deficiency was afterwards made good by Menelaus's *Sphaerica*).¹ Hence the Greek spherical trigonometry began with Menelaus (90 A.D.). His theorem in geometry is well-known—"If the sides of a plane triangle be cut by a transversal into six segments, the continued product of any three alternate segments, is equal to the continued product of the remaining three." From this proposition he deduced the so-called "*regula sex quantitatum*" or the theorem, if the sides of a spherical triangle be cut by an arc of a great circle into six segments, the continued product of the chords of the doubles of any three alternate segments is equal to the continued product of the chords of doubles of the remaining three segments." In plane geometry if the sides BC, CA, AB of a triangle be cut by any transversal at L, M, N, respectively, L then we have

$$\frac{BL}{LC} \cdot \frac{CM}{MA} \cdot \frac{AN}{NB} = 1.$$

In spherics the theorem is :

$$\frac{\text{Chord } 2 \text{ BL}}{\text{Chord } 2 \text{ LC}} \cdot \frac{\text{Chord } 2 \text{ CM}}{\text{Chord } 2 \text{ MA}} \cdot \frac{\text{Chord } 2 \text{ AN}}{\text{Chord } 2 \text{ NB}} = 1$$

Both these theorems are proved in Ptolemy's *Syntaxis* (Karl Manitius's edition, Vol. I, pp. 45-51).

Fig. 5

If R be the radius of the sphere on which the spherical triangle ABC is constructed, then the chord of the arc $2 \text{ BL} = 2 R \sin \text{BL}$. Hence Menelaus's theorem in spherics may be expressed as follows :

$$\frac{\sin \text{BL}}{\sin \text{LC}} \cdot \frac{\sin \text{CM}}{\sin \text{MA}} \cdot \frac{\sin \text{AN}}{\sin \text{NB}} = 1$$

This theorem is true for any spherical triangle.

If $\angle B = \angle N = 90^\circ$ and L the pole of AB, then LMN is a secondary to the arc AB. There are four arcs of great circles; taking any three as forming a spherical triangle and the fourth as the transversal we readily get for the right-angled

1. A.A. Björnbo, "Studien über Menelaos' Sphaerik" in *Abhandlungen Zur Geschichte der Mathematischen Wissenschaften* for 1902, pp. 89 et seq.; also Heath, *Greek Mathematics*, vol. II p. 261-73.

triangle ABC, the relations :--

$$(i) \sin a = \sin b \sin A$$

$$(ii) \sin c = \tan a \cot A$$

$$(iii) \cos b = \cos a \cos c$$

$$(iv) \tan c = \tan b \cos A$$

The above are some of the Napier's rules for a right-angled spherical triangle, deducible from Menelaus's theorem¹. They are generally sufficient in the case of such triangles. In any spherical triangle, however, this theorem of Menelaus does not in any single step lead to any of the equivalents of the time-altitude or altazimuth equations in spherical astronomy. The ancient Indian methods, though none of them are so highly finished as Menelaus's theorem, yet are not less powerful in tackling the problems that arise in astronomy in connection with the apparent diurnal motion of the heavens. The Greek or Ptolemaic method presents no further points of interest except in its application. We now proceed to illustrate the ancient Indian methods and shall refer to the Ptolemaic method as occasion arises.

Ancient Indian Methods in Spherical Astronomy

In the Indian methods there is no general rule to follow. It is by properties of similar right-angled triangles that a fairly complete set of accurate formulae are obtained. These right-angled plane triangles are classified under the names,—'Krānti-kṣetras' (triangles of declination) and 'Akṣa-kṣetras' (triangles of latitude). We consider the following problems :—

Problem :- To find the time of rising on the equator of a length l , of arc of the ecliptic measured from the first point of Aries.

Let ω be the obliquity of the ecliptic and R. A. the right ascension corresponding to the longitude l , and δ the corresponding declination. The Indian form of the equation is :

1. Three more can be deduced similarly, namely,

$$(v) \sin c = \sin b \sin C$$

$$(vi) \sin a = \tan c \cot C$$

$$(vii) \tan a = \cos C \tan b.$$

Greek Method

In the same figure¹ let PSC be the triangle and γMQ be the transversal. Then Menelaus's theorem gives

$$\frac{\sin PM}{\sin MS} \times \frac{\sin Sy}{\sin \gamma C} \times \frac{\sin CQ}{\sin QP} = 1$$

$$\text{or} \quad \frac{1}{\sin \delta} \times \frac{\sin l}{1} + \frac{\sin \omega}{1} = 1$$

$$\text{or} \quad \sin \delta = \sin l \times \sin \omega.$$

Indian Method

Again by the Indian method from the same two similar triangles we get

$$mn : nS = OK : OC$$

$$\text{or,} \quad mn : R \sin l = R \cos \omega : R$$

$$\therefore mn = \frac{R \sin l \times R \cos \omega}{R}$$

$$\text{Again } MN : mn = OM : Om$$

$$\text{i.e., } R \sin R. A. : mn = R : R \cos \delta$$

$$\therefore R \sin R.A. = \frac{R \sin l \times R \cos \omega}{R \cos \delta}$$

Greek Method

Take PQM for the triangle and γSC for the transversal.

$$\text{Then,} \quad \frac{\sin PC}{\sin CQ} \times \frac{\sin QY}{\sin \gamma M} \times \frac{\sin MS}{\sin SP} = 1$$

$$\text{or} \quad \frac{\cos \omega}{\sin \omega} \times \frac{1}{\sin R.A.} \times \frac{\sin \delta}{\cos \delta} = 1$$

$$\text{or} \quad \sin R.A. = \tan \delta \cot \omega,$$

The Indian form of the equation is different from that of Ptolemy's. It is also better for the purpose of calculation.

Note :—From the same two similar triangles we have

$$On : ON = R \cos \delta : R$$

$$\therefore On : R \cos l = \frac{R \cos R.A. \times R \cos \delta}{R} \quad \dots\dots(3)$$

$$\text{Again, } \tan R.A. = \frac{mn}{on}$$

$$= \frac{R \sin l \times R \cos \omega}{R \times R \cos l} \quad \dots\dots(4)$$

$$\text{Again, } mn : Sm = OK : KC$$

1. Manitius' Edition of *Syntaxis*, I, 51-53.

$$\text{or } mn = \frac{R \sin \delta \times R \cos \omega}{R \sin \omega}$$

$$\therefore R \sin R. A. = \frac{MN}{mn} \times mn = \frac{R}{R \cos \delta} \times \frac{R \sin \delta \times R \cos \omega}{R \sin \omega} \quad (5)$$

Problem II :—

Sidereal Time-intervals

Indian Method

The problem discussed above provides the method of finding the sidereal time-intervals in which the signs of the zodiac rise on the equator. To find the corresponding times at any latitude ϕ , it is necessary to calculate and apply what is the ascensional difference due to the elevation of the celestial pole. This ascensional difference is called '*carakāla*' or the variation in the length of half the day. The 'sine' of this '*carakāla*' is called '*carajyā*.' If *ch* denotes this '*carakāla*,'

$$\text{then,}^1 R. \sin ch = \frac{R \sin \phi \times R \sin \delta \times R}{R \cos \phi \times R \cos \delta}$$

Just as in the solution of the previous problem, the declinational triangles or '*Krānti Kṣetras*' were constructed and used, so in the solution of this and other problems another set of similar triangles were conceived and constructed and were given the name '*Akṣa kṣetras*.'²

Let NPZH be the meridian (Fig.7), NOH the north-south line passing through the observer O, P the celestial pole, OQ the trace of the equator on the meridian plane, Z the zenith. Join OZ. From Q draw QM perpendicular to OZ. Then the triangle QOM is an '*Akṣa-kṣetra*' or a latitudinal right-angled triangle, as $\angle QOM = \phi$, the latitude of the station.

Another '*Akṣakṣetra*' is thus

conceived, in the same figure, let P, P' be the north and south celestial poles, N, the north point, AB A'B' the diurnal

Fig 7

1. *Āryabhaṭīya*, Gola, 26; *Pañca-siddhāntikā*, IV, 34; *Brahmasphuṭasiddhānta*, II, 57-58; *Sūrya-siddhānta*, II, 91; *Grahagaṇita*, VIII, 48-49.

2. *Bhāskara, Golādhyāya* (Wilkinson and Bapudeva Śāstri's tr.) PP. 173-76; also, *Bhāskara, Grahagaṇita*, Ch. IX, 13-17.

circle of a heavenly body with declination δ , NEHW the horizon, PEP' W the six O' clock circle. Here AA' the line of intersection of the diurnal circle with the horizon is called the "udayasta-sūtra"¹ (or the thread joining the rising and setting points). SS' the line of intersection of the diurnal circle and the six o' clock circle, is the horizontal diameter of the diurnal circle. From S draw SK and SL perpendiculars respectively to AA' and EW. Join KL.

Now since $PN = \phi$, the latitude of the station, in the small right-angled triangle KLS, the \angle KLS is also $= \phi$.

$$\therefore SK : SL = QM : MO$$

$$\text{or } SK = \frac{SL \times QM}{MO} = \frac{R \sin \delta \times R \sin \phi}{R \cos \phi}$$

Now SK^2 is a "sine" in the small circle AB A'B' of which the radius is $R \cos \delta$; this "sine" reduced to the equator (radius R) is the 'sine' of *cara*.

$$\begin{aligned} \therefore R \sin ch &= R \sin EPA \\ &= \frac{R \sin \delta \times R \sin \phi \times R}{R \cos \phi \times \cos \delta} \end{aligned}$$

Greek Method

Let³ the arc PA be produced to meet the equator at C. Take PCQ' for the triangle and EAN for the transversal. Then we get,

$$\begin{aligned} \frac{\sin PA}{\sin AC} \times \frac{\sin CE}{\sin EQ'} \times \frac{\sin Q'N}{\sin NP} &= 1 \\ \text{or } \frac{\cos \delta}{\sin \delta} \times \frac{\sin CE}{1} \times \frac{\cos \phi}{\sin \phi} &= 1 \\ \therefore \sin CE = \sin ch &= \frac{\sin \phi \times \sin \delta}{\cos \phi \times \cos \delta} \end{aligned}$$

Note—The perpendicular distance between AA' and EW is called the 'sine' of the amplitude or the 'Agra' which is thus calculated :—

$$\begin{aligned} KL : LS &= QO : OM \\ \therefore {}^4R \sin \text{amplitude} &= \text{'Agra'} = KL \\ &= \frac{LS \times QO}{OM} = \frac{R \sin \delta \times R}{R \cos \phi} \end{aligned}$$

It is now evident that the ancient Indian method is different

1. Bhāskara, *Gola*, VII, 39.

2. This is called by the name 'kujyā' or 'ksitiijyā', i. e., earth-sine. Āryabhaṭa, *Gola*, 26, Brahmagupta, II, 57, *Sūrya-siddhānta*, II, 61 etc.

3. Manitius, *ibid*, p. 84.

4. Āryabhaṭa, *Gola*, 30, etc.

from the Greek method in this case also. As the triangle KLS is difficult to show in the diagram, it is shown in its projection on the meridian plane in Burgess's translation of the "*Sūrya-siddhānta*," (page 232) and also in Wilkinson and Bāpūdeva Śāstrī's translation of the '*Siddhānta Śiromani*,' p. 175. This has led Braunmühl to assume that the Indian method of arriving at the equation of ascensional difference and some other equations of spherical astronomy has its origin in the Analemma of Ptolemy. A careful study, however, does not justify the identification of Indian methods with the graphic method of the Analemma, which is deduced from the projections of the position of a heavenly body on the meridian prime vertical and the horizon. It is being presently shown that what was done out of difficulty in drawing the figures properly has been taken by Braunmühl as a Greek connection.

Problem III¹ :—

To find the "Time-altitude" Equation

If from any point S on the diurnal circle a perpendicular be drawn to the *Udayāsta-Sūtra* spoken of before, this perpendicular is called the *cheda* or '*iṣṭahṛti*.' The perpendicular from S on the horizon is called '*Śanku*'² the sine of the altitude. The line joining the foot of the '*Śanku*' and that of the perpendicular on the '*Udayāsta-Sūtra*' goes by the name of '*Śankutala*' and this *Śankutala* lies to the south of the '*Udayāsta-Sūtra*' during the day.

In this figure (Fig 8) if AA' be the '*Udayāsta-Sūtra*' or the intersection of the diurnal circle and the horizon, and S a point on the diurnal circle denoting a position of the Sun, SK, SL perpendiculars on AA' and the horizon respectively; SL is called the '*Śanku*,' SK the '*cheda*' and LK, the '*Śankutala*'. In this triangle KSL, the angle KSL was recognised to be the latitude of the station.

Thus the triangle SKL is not taken in its projection on the meridian plane. The side SK is taken 'as formed of two parts.

1. Āryabhaṭa could not arrive at the true equation, Cf. Gola 28. The correct rules occur in *Pañcasiddhāntikā*, IV, 42, 44; *Brahmasphuṭasiddhānta*, III, 36-38, 26-40; *Sūryasiddhānta*, III, 34-35.

2. Bhāskara says : ग्रहस्थानाल्लम्बः शंकुः । तस्य तलमुदयास्तसूत्राद्विणतो भवति ॥
"Gola, VIII-39-41, Āryabhaṭa uses the term शङ्कुग्रहम्" Gola, 29.

Fig. 8

'*Kujyā*.' This '*Kalā*' is constructed from the point S in the diurnal circle. Thus the triangles like SKL were not taken in their projections on the meridian plane as Braunmühl would suggest.

From the triangle KSK, we get.

'*Cheda*' : '*Sanku*' = $R : R \cos \phi$ where ϕ is the latitude of the observer;

'*Sanku*' is here = $R \cos Z$, Z being the Sun's zenith distance.

$$\therefore \text{'cheda'} = \frac{R \cos Z \times R}{R \cos \phi}$$

Now '*Cheda*' = radius of the diurnal circle + *Kujyā* — versed sine of the hour-angle in the diurnal circle $O'B + O'V - BR$,

$$= R \cos \delta + \frac{R \sin \delta \times R \sin \phi}{R \cos \phi} - \frac{R \text{ vers } H \times R \cos \delta}{R}$$

As in the previous problem, $Kujyā = SK = \frac{R \sin \delta \times R \sin \phi}{R \cos \phi}$

$$\text{or } \frac{R \cos Z \times R}{R \cos \phi} = \frac{R \cos \delta}{R} \left\{ R + \frac{R \sin \delta \times R \sin \phi}{R \cos \phi} \times \frac{R}{R \cos \delta} - R \text{ vers } H \right\}$$

The above equation simplified becomes

$$\cos Z = \sin \delta \sin \phi + \cos \delta \cos \phi \cos H.$$

In this connection we consider the altazimuth equation by the Indian method.

1. Bhāskara's *Grahagaṇita*, VIII, 55.

O' is the middle point of CC' or it is the centre of the diurnal circle ABB' .

Let CC' be the line of intersection of the diurnal circle and the 'six o'clock' circle EPW. Let SK cut CC' in M. Then,

$$SK = SM + MK$$

Here SM, the 'sine' in the diurnal circle of the complement of the hour angle is given a distinct name '*Kalā*' and MK as explained before is known by the name

¹Problem IV :—

The Altazimuth Equation

Indiad Method

Let α denote the azimuth of the Sun from the south. In the same triangle SKL in the same figure, we have,

$$LK : SL = R \sin \phi : R \cos \phi$$

$$\text{or, 'Sankutala' : 'Sanku'} = R \sin^2 \phi : R \cos \phi$$

$$\therefore \text{'Sankutala'} = \frac{R^1 \cos Z \times R \sin \phi}{R \cos \phi}$$

Now 'Sankutala' is made up of two parts, namely, 'Bahu' and 'Agrā,' of which the former is the distance of L from the observer's East-West line; the 'Agrā' has been already found.

$$\text{Here 'Bahu'} = \frac{R \sin Z \times R \cos \alpha}{R} \text{ and 'Agrā'} = \frac{R \sin \delta \times R}{R \cos \phi}$$

$$\therefore \text{'Sankutala'} = \text{'Bahu'} + \text{'Agrā'}$$

$$\text{or } \frac{R \cos Z \times R \sin \phi}{R \cos \phi} = \frac{R \sin Z \times R \cos \alpha}{R} + \frac{R \sin \delta \times R}{R \cos \phi}$$

$$\text{or } R \sin \delta = \frac{R \cos \phi}{R} \left(\frac{R \cos Z \times R \sin \phi}{R \cos \phi} - \frac{R \sin Z \times R \cos \alpha}{\phi} \right)$$

which is easily seen to be equivalent to

$$\sin \delta = \cos Z \sin \phi - \sin Z \cos \phi, \cos \alpha$$

Greek Method

Ptolemy² has also a method of finding the Sun's altitude at any hour of the day. His method is as follows :—

Fig. 9

(i) He would find by means of his tables for the times of risings of the signs of the zodiac, the orient ecliptic point. (ii) He would then find the culminating point of the ecliptic. (iii) He would finally apply Menelaus's theorem in spherics thus :—

Let ASC be any position of the ecliptic, (Fig. 9) NZC the

1. The equivalent of this, in a particular case, is first found in *Brāhma. sphuṭasiddhānta*, Ch. III, 54-56 Cf. *Sūryasiddhānta*, III, 28-31, also *Bhāskara Grahaganita*, IX, 50-52.
2. Manitius, *ibid.*, pp. 118, 19.

meridian, NAMH the horizon, Z, the zenith and S the Sun. Here the celestial longitudes of C, S and A are taken to be known; hence ZC and CH are also known.

Now take ZCS for the triangle and HMA to be the transversal ; we then have by Menelaus's theorem.

$$\frac{\sin ZH}{\sin HC} \times \frac{\sin CA}{\sin AS} \times \frac{\sin SM}{\sin MZ} = 1$$

$$\text{or } \sin SM = \frac{\cos CZ \times \sin AS}{\sin CA}$$

It is thus clear that Ptolemy had no direct method for connecting the Sun's altitude and the hour-angle. This method is workable for the problem "given time, find the altitude" but is not workable in the converse problem ; besides, the calculation of the longitudes of A and C is very cumbrous.

Again, when EA has been found out, taking ZHM for the triangle and CSA for the transversal, we get,

$$\frac{\sin HA}{\sin Am} \times \frac{\sin MS}{\sin SZ} \times \frac{\sin ZC}{\sin CH} = 1, \text{ whence and thence HM,}$$

the azimuth can be found. The method is here also cumbrous, there being no direct connection between altitude and azimuth ; besides the time-element is not avoided.

The Analemma of Ptolemy and the Indian Method.

When the Sun's declination is zero and his hour-angle, is H, Zeuthen¹ following the method of the 'Analemma' of Ptolemy, as explained by Braunmühl² has deduced the following equations :

$$(1) \cos Z = \cos H \cdot \cos \phi$$

$$(2) \tan a = \frac{\tan H}{\sin \phi}$$

To these two, Heath following Braunmühl adds

$$(3) {}^s\tan ZQ = \frac{\tan H}{\cos \phi}$$

1. Heath, *Greek Mathematics*, Vol. II, pp. 290-91.

Zeuthen, *Bibliotheca Mathematica*, 13, 1900, pp. 23-27.

2. Braunmühl, *ibid*, pp. 12-13.

3. The Indian form of this equation is $R \sin ZQ = \frac{R \sin H \times R}{\sqrt{R^2 - R^2 \cos^2 H \times R^2 \sin^2 \phi}}$
R

Bhāskara's, *Golādhyāya*, Com. on VIII, 67.

where Z is the zenith and Q is the point of intersection of the prime vertical and its secondary passing through the Sun and the north-south points.

Zeuthen¹ points out that later in the same treatise Ptolemy finds the arc 2β described above the horizon by a star of given declination δ' by a procedure equivalent to the formula.

$$(4) \cos \beta = \tan \delta' \tan \phi.$$

With regard to the 'Analemma' of Ptolemy, it may be noted, as Heath² says, that "the procedure amounts to a method of graphically constructing the arcs required as parts of an auxiliary circle in one plane." Many things may be, in practice, done graphically far more easily than by the theoretical method. Besides, no theoretical calculations occur in the 'Analemma'. Zeuthen³, following the method of this work, has deduced in the general case, the two equations.

$$(5) \cos Z = (\cos \delta, \cos H + \sin \delta, \tan \phi) \cos \phi.$$

$$(6) \tan \alpha = \frac{\cos \delta \sin H}{\frac{\sin \delta}{\cos \delta} + (\cos \delta \cos H + \sin \delta \tan \phi) \sin \phi}$$

These equations are suggested to a modern reader from a study of the figures in the 'Analemma.' But neither in this work nor in the 'Syntaxis' are they to be found. With regard to the first four formulae, it is possible that they were recognised by Ptolemy. With regard to the last two, Zeuthen³ remarks "mais le texte n'en contient rien," and they were certainly not recognised by Ptolemy.

Besides the tangent function is wholly absent in Greek trigonometry. They are also different in form from those arrived at by the Indian method as explained before. Thus, it is clear that the Indian methods are in no way connected with the method of the 'Analemma.'

Even taking for granted that the Indians followed a method of projection much allied to the method of the 'Analemma' there is no adequate reason for assuming that their method is derived from any Greek source. Analogy and precedence do not necessarily constitute originality—there is still the chance of a remoter origin from which both the systems drew their inspiration. The method of the 'Analemma,' as has been already stated, presents a

1, 2, Björnbo, *loc. cit.* p. 86.

3. Zeuthen, *loc. cit.* p. 27.

graphical method for constructing the Sun's altitude and azimuth from the hour angle when the Sun's declination is zero but such a graphical method is generally complex as compared with the elegant Indian method. An astronomer who constructs and uses an armillary sphere to arrive at his equations in spherical astronomy and who has not a well-developed spherical astronomy at his command must have to draw perpendiculars from the positions of the heavenly body, not only on the meridian plane, the horizon or on the prime vertical, as the occasion arises, but also on the line of intersection of the diurnal circle with the horizon. Hence Braunnmühl's statement that the Indian methods of spherical astronomy have their origin in the 'Analemma's, in spite of his admitting that Indians were first to utilise its methods, is rather far-fetched and tends to take away the honour from the great Indian astronomers, who devised the beautiful methods. The 'Analemma' as it now exists is a Latin translation from an Arabic version of the original Greek¹. We may reasonably doubt that the Arabic version was greatly influenced by the ancient Indian system.

We now pass on to the consideration of other allied or similar problems in the two systems of astronomy.

Problem V—

To find the Angle between the Ecliptic and the Meridian

Fig. 10

Indian Method²

Let γSA be the ecliptic, γCE the equator, E the east-point of the horizon (Fig 10). Cut off $SH=90^\circ$ and draw the great circle $HEAP'$ cutting the meridian $P'SCH$ at the points P' and H . The aim is to find AP' but it is enough to find EA since AP' is the complement of EA' .

Both Āryabhaṭa and Brahmagupta were unable to find EA correctly. Let P be the celestial pole and let PAE' be

1. On the influence of the ancient Indians on Arab mathematics and astronomy; see Alberuni's *India*, translated by Dr. E. Sachau, Vol. II, p. 304.

2. Āryabhaṭa, *Gola*, 45; *BrSpSi*, IV. 17; *Sūrya-siddhānta*, IV. 25; Bhāskara's *Golādhyāya*, VIII, 21-74, first example in his own commentary.

the secondary to the equator cutting it at E'. Both the above astronomers were content with the idea that $AE=AE'$, or that AE =the declination of the point A of the ecliptic which is 90° ahead of S in the above figure. This idea continued till the time of Bhāskara II (1150 A. D.) who found out the correct equation.

He recognised that CS, the declination of $S=PP'$; P'EH is then the horizon of the station whose north geographical latitude is CS. Also, the 'sine' of EA is the 'Agyā' or the sine of the amplitude of the point A for the latitude CS.

$$\therefore R \sin EA = \frac{R \sin AE' \times R}{R \cos CS} = \frac{R \sin (90^\circ + \gamma S) \times R \sin \omega}{R} \\ \times \frac{R}{R \cos CS}$$

$$\text{or } R \sin EA = \frac{R \sin (90^\circ + l) \times R \sin \omega}{R \cos \delta}$$

where l stands for γS and δ for CS.

Greek Method :

We give below the Ptolemy's method in a slightly modified form¹. Let SHA be the triangle and γCE be the transversal ; then we have,

$$\frac{\sin SC}{\sin CH} \times \frac{\sin HE}{\sin EA} \times \frac{\sin A\gamma}{\sin \gamma S} = 1 \\ \text{or } \frac{\sin \delta}{\cos \delta} \times \frac{\sin 90^\circ}{\sin EA} \times \frac{\sin (90^\circ + l)}{\sin \iota} = 1 \\ \therefore \sin EA = \frac{\sin \delta \times \sin (90^\circ + l)}{\cos \delta \times \sin \iota},$$

which is readily transformed into Bhāskara's equation. The originality of Bhāskara would be readily admitted.

Problem VI—

**To find the Angle between the
Ecliptic and the Horizon**

Indian Method :

(A) Āryabhaṭa's method. It consists of the following² steps :—

- (1) Determination of the orient point of ecliptic.
- (2) Finding the sine of its amplitude.

¹ Manilius, *ibid*, Book I, pp. 104-06.

² Āryabhaṭa, *Gola*, 33 : *Sūryasiddhānta*, V, 5-6.

- (3) Determination of the culminating point of the ecliptic from the hour-angle of the Sun.
- (4) Finding the declination of the culminating point of the ecliptic.

Having obtained the above elements, his rule can be followed thus :

In this Fig. 11 NZH is the meridian, HMEAN the horizon, CN'A the ecliptic. If N' be the nonagesimal or the highest point of the ecliptic, the altitude of N' is the inclination of the ecliptic to the horizon.

Fig. 11

Here HM=EA.

According to Āryabhaṭa,

$$R \sin CN' = \frac{R \sin CZ \times R \sin HM}{R}$$

$$\text{and } R \sin ZN' = \sqrt{(R \sin CZ)^2 - (R \sin CN')^2}$$

This is only an approximate rule. As expressed here,

$$R \sin ZN' = \frac{R \sin CZ \times R \cos HM}{R} \text{ approximately.}$$

$$= \frac{R \sin CZ \times R \cos HM \times R}{R \times R \cos CN'} \text{ accurately.}$$

$$= \frac{R \sin CZ \times R \cos HM}{R \cos CN'}.$$

(B) The method of Brahmagupta² :

Brahmagupta would also first determine the orient ecliptic

1. This correction was perhaps first noticed by Raṅganātha (1603 A. D.) in his commentary in the *Sūryasiddhānta*.

2. *BrSpSi*. V 3.

point A. Then he subtracts 90° from the longitude of A. Thus having the longitude of N', he next finds the part of the day elapsed of N'; from which by the time-altitude equation discussed above, he finds ZN'. This is of course more accurate than that of Āryabhaṭa. Bhāskara¹ here follows Brahmagupta.

Greek Method :

Let the ecliptic CN'A cut the lower half of the meridian at F. Ptolemy takes AK along the ecliptic $= 90^\circ$ and AR along the horizon $= 90^\circ$; then the great circle passing through R and K passes through the nadir Z'. Now take Z'FK for the triangle and ANR for the transversal, then by Menelaus's theorem.²

$$\frac{\sin FN}{\sin NZ'} \times \frac{\sin Z'R}{\sin RK} \times \frac{\sin KA}{\sin AF} = 1$$

$$\therefore \sin RK = \frac{\sin FN}{\sin AF} = \frac{\cos FZ'}{\sin AC} = \frac{\cos CZ}{\sin AC} = \frac{\sin CH}{\sin AC}$$

$$\text{or } \sin MN' = \frac{\sin CH}{\sin AC}.$$

Here Ptolemy's equation is simpler than that of Āryabhaṭa; hence they must be independent of each other.

Fig. 12

Problem VII:—

To find the Angle made by the Vertical through any Point of the Ecliptic with the Latter

This problem is considered by Ptolemy but it is not considered separately in Indian Astronomy, but from the rule for parallax in longitude, the rule for its calculation can be deduced.

Indian Method :

In Fig. 12 S represents the true position of the Sun and S' the Sun's position as depressed by parallax. N'SA is the ecliptic. If from S', S'Q be drawn perpendicular to the ecliptic, then, if P is the horizontal parallax,

1. *Grahaganita*; XII, 3-4.

2. Manitius, *ibid.* pp. 110-111.

$$SQ = SS' \times \frac{R \cos S'SQ}{R} = \frac{P \times R \sin ZS}{R} \times \frac{R \cos S'SQ}{R}$$

$$1 = \frac{P}{R} \sqrt{(R \sin ZS)^2 - (R \sin ZN')^2}$$

$$2 = \frac{P}{R^2} \times R \sin N'S \times R \cos ZN', \text{ where } N' \text{ is the nonagesimal}$$

Thus $R \cos S'SQ$ is seen to be

$$= \frac{R \sin N'S \times R \cos ZN'}{R \sin ZS}$$

The Indian method is fully described by Bhāskara in his '*Goladhyāya*, VIII, 12-25. The truth of the Indian rule for $R \cos S'SQ$ is easily seen from the spherical triangle ASQ where A is the pole of the ecliptic.

Greek Method :

³Ptolemy takes SK and SL 90° each, along the vertical circle $ZSEK$ and the ecliptic $N'SA$. The great circle through K and L cuts the horizon at R which is the pole of the vertical circle. He takes SKL for the triangle and EAR for the transversal, then

$$\frac{\sin SE}{\sin EK} \times \frac{\sin KR}{\sin LR} \times \frac{\sin LA}{\sin AS} = 1$$

$$\text{or } \sin LR = \frac{\cos ZS \times \cos AS}{\sin ZS \times \sin AS}$$

$$\text{or } \cos S'SQ = \cot ZS \times \cot AS = \tan SE \times \cot AS.$$

The Indian and the Greek rules are altogether different both in form and method. There can, therefore, be no question of any connection between them.

Problem VIII :—

To convert the Celestial Longitude of a Heavenly Body into its Polar Longitude

If σ be the position of a (Fig.13), γK and σK are the celestial longitude and the celestial latitude, respectively ; γM and σM are the polar longitude and polar latitude ; γN and σV are the right ascension and declination of the star.

Indian Method :

All Indian astronomers attempt at finding MK which, sub-

2. *BrSpSi*, V, 4-5 ; *Sūryasiddhānta*, V, 7-8 Bhāskara, *Grahagaṇita*, XII, 4.
3. Manilius, *ibid*, p. 119.

point A. Then he subtracts 90° from the longitude of A. Thus having the longitude of N' , he next finds the part of the day elapsed of N' ; from which by the time-altitude equation discussed above, he finds ZN' . This is of course more accurate than that of Āryabhaṭa. Bhāskara¹ here follows Brahmagupta.

Greek Method :

Let the ecliptic $CN'A$ cut the lower half of the meridian at F. Ptolemy takes AK along the ecliptic $= 90^\circ$ and AR along the horizon $= 90^\circ$; then the great circle passing through R and K passes through the nadir Z' . Now take $Z'FK$ for the triangle and ANR for the transversal, then by Menelaus's theorem,²

$$\frac{\sin FN}{\sin NZ'} \times \frac{\sin Z'R}{\sin RK} \times \frac{\sin KA}{\sin AF} = 1$$

$$\therefore \sin RK = \frac{\sin FN}{\sin AF} = \frac{\cos FZ'}{\sin AC} = \frac{\cos CZ}{\sin AC} = \frac{\sin CH}{\sin AC}$$

$$\text{or } \sin MN' = \frac{\sin CH}{\sin AC}.$$

Here Ptolemy's equation is simpler than that of Āryabhaṭa; hence they must be independent of each other.

Fig. 12

Problem VII:—

To find the Angle made by the Vertical through any Point of the Ecliptic with the Latter

This problem is considered by Ptolemy but it is not considered separately in Indian Astronomy, but from the rule for parallax in longitude, the rule for its calculation can be deduced.

Indian Method :

In Fig. 12 S represents the true position of the Sun and S' the Sun's position as depressed by parallax. $N'SA$ is the ecliptic. If from S' , $S'Q$ be drawn perpendicular to the ecliptic, then, if P is the horizontal parallax,

1. *Grahaṇṣita*, XII, 3-4.

2. Manilius, *ibid.*, pp. 110-111.

$$SQ = SS' \times \frac{R \cos S'SQ}{R} = \frac{P \times R \sin ZS}{R} \times \frac{R \cos S'SQ}{R}$$

$$^1 = \frac{P}{R} \sqrt{(R \sin ZS)^2 - (R \sin ZN')^2}$$

$$^2 = \frac{P}{R^2} \times R \sin N'S \times R \cos ZN', \text{ where } N' \text{ is the nonagesimal.}$$

Thus $R \cos S'SQ$ is seen to be

$$= \frac{R \sin N'S \times R \cos ZN'}{R \sin ZS}$$

The Indian method is fully described by Bhāskara in his '*Goladhyaya*. VIII, 12-25. The truth of the Indian rule for $R \cos S'SQ$ is easily seen from the spherical triangle ΛZS , where Λ is the pole of the ecliptic.

Greek Method :

³Ptolemy takes SK and $SL = 90^\circ$ each, along the vertical circle $ZSEK$ and the ecliptic $N'SA$. The great circle through K and L cuts the horizon at R which is the pole of the vertical circle. He takes $\angle SKL$ for the triangle and $\angle EAR$ for the transversal, then

$$\frac{\sin SE}{\sin EK} \times \frac{\sin KR}{\sin LR} \times \frac{\sin LA}{\sin AS} = 1$$

$$\text{or } \sin LR = \frac{\cos ZS \times \cos AS}{\sin ZS \times \sin AS}$$

$$\text{or } \cos S'SQ = \cot ZS \times \cot AS = \tan SE \times \cot AS.$$

The Indian and the Greek rules are altogether different both in form and method. There can, therefore, be no question of any connection between them.

Problem VIII :—

To convert the Celestial Longitude of a Heavenly Body into its Polar Longitude

3. Manitius, *ibid*, p. 119.

tracted from, or added to, γK the celestial longitude, gives γM the polar longitude.

According to Āryabhata¹,

$$MK = \frac{\sigma K \times R \text{ vers } \gamma K \times R \sin \omega}{R^2}.$$

Brahmagupta² makes a distinct improvement on Āryabhata and gives his rule for finding the projection MK on the celestial equator.

If P be the celestial pole, PKH the secondary to the equator, Brahmagupta says that,

Fig- 13

$$NH = \frac{\sigma K \times R \sin (\gamma K + 90^\circ) \times R \sin \omega}{R}$$

If from σ , σR is drawn perpendicular to PKH, it is evident that,

$$R \sin \sigma R = \frac{R \sin \sigma K \times R \sin \sigma KR}{R}.$$

According to Āryabhata and Brahmagupta, as explained before,

$$R \sin \sigma KR = \frac{R \sin (\gamma K + 90^\circ) \times R \sin \omega}{R}$$

Hence Brahmagupta intends that,

$$NH = \sigma R = \frac{\sigma K \times R \sin \sigma KR}{R}$$

which is rather a big assumption. He then directs the finding of the part of the ecliptic of which σR or NH is the projection on the equator thus approximately to MK.

Āryabhata, Brahmagupta³ and the modern *Sūryasiddhanta* take the declination $\sigma N = \sigma K + KH$ where σK is small. They do not consider the case where σK is large.

Bhāskara alone gives us fairly correct rules for this transformation of co-ordinates.

1. Āryabhata, *Gola*, 36.

2. *BrSpSi* X, 17.

3. *BrSpSi*, X, 15, *Sūryasiddhanta*, II, 58.

In order to find σN , he would multiply

σK by $\frac{R \cos \sigma KP}{R}$; according to him,

$$\sigma N = \frac{\sigma K \times R \cos \sigma KP}{R} + KH^1$$

This is a decided improvement on Brahmagupta's corresponding rule. The declination σN obtained would be very nearly accurate.

Having obtained σN , Bhāskara² then directs the finding of NH , thus,

$$NH = \frac{\sigma K \times R \sin \sigma KP}{R \cos \sigma N}$$

He then directs the finding of MK on the ecliptic of which NH is the projection by means of the times of rising of the signs of the zodiac on the equator.

Thus, the Indian methods show a beginning and development only. The Greek method as given by Ptolemy is mathematically accurate.

Greek Method³

To transform the celestial longitude and celestial latitude to right ascension and declination.

Let the great circle $\pi \sigma K$ meet the equator at Δ . Ptolemy would then from the given value of γK , find $\gamma \Delta$ and ΔK by using his tables for the rising of signs of the zodiac on the equator. He then takes $\pi P \sigma$ for the triangle and $\gamma N \Delta Q$ for the transversal. The Menelaus' Equation, then, is

$$\frac{\sin \pi Q}{\sin QP} \times \frac{\sin PN}{\sin N\sigma} \times \frac{\sin \sigma \Delta}{\sin \Delta \pi} = 1^2$$

Here $\pi Q = 90^\circ + \omega$, $QP = 90^\circ$, $PN = 90^\circ$; $\sigma \Delta = \sigma K + K \Delta$.

$\pi \Delta = 90^\circ + K \Delta$, whence $N\sigma$ is obtained.

He next takes PNQ for the triangle and $\pi \sigma \Delta$ for the transversal.

$$\therefore \frac{\sin P\pi}{\sin \pi Q} \times \frac{\sin Q\Delta}{\sin \Delta N} \times \frac{\sin N\sigma}{\sin \sigma P} = 1$$

Here $P\pi = \omega$, $\pi Q = 90^\circ + \omega$, $Q\Delta = 90^\circ - \gamma \Delta$.

Hence the above equation gives him ΔN . Now,

$$\gamma N = \gamma \Delta - \Delta N,$$

1. Bhāskara, *Grahaganita* XIII, 3.

2. Ibid. XIII, 4.

3. Manitius, Ibid, Vol. II, *Achtes Buch*, pp. 84-85.

It is almost needless to say that neither in the method nor in the rules is there any agreement between the Indian and Greek spherical astronomy in the solution of this problem.

Kaye's view¹

As to Kaye, it appears that he has not been able to find a method in the translation of the *Sūryasiddhānta* by Burgess. The figures of his paper referred to before do not show the "Akṣakṣetras" even in their projections on the meridian place. He refers to Braunmühl's *History of Trigonometry* but does not appear to have been able to follow him in his "*Methode der indischen Trigonometrie*." Kaye, however, is not slow in belittling Indian trigonometry when he says :—The Indian astronomers employed the sine function principally and the versed sine occasionally ; they never employed the tangent function; and generally, but not always, preferred to employ the sine of the complementary angle rather than the cosine functions.'

Fig. 14

In (Fig. 14), of the arc AP_1 , P_1M_1 is the "sine" and P_1N_1 is the "cosine" of AP_1 , P_2M_2 is the "sine" and P_2N_2 is the "cosine"; of AP_3 , P_3M_3 is the "sine" and P_3N_3 is the "cosine"; etc. It is evident that a better definition of these functions was never given.

We have thus seen that some of the solutions of Āryabhaṭa

1. J. A. S. B., N. S., XV, p. 154.

2. तस्य बिन्दोः ग्रन्थ-परायाश्च यदन्तरं रुद्रोर्ज्या ।

बिन्दोर्वायोत्तरायाश्च यदन्तरं सा कोटिज्या ॥

—(Bhāskara, *Grahaṇiṭa*, commentary. II, 88-21

are imperfect, of Brahmagupta the solutions are more accurate, while those of Bhāskara are generally mathematically correct. The date of the scientific ancient Indian Astronomy is indeed 499 A. D., while that of the *Syntaxis* is about 150 A. D. It is by these shortcomings and differences in the methods, new ideas (e.g., the idea of the differential calculus)* and the like, that we can safely say that Indian Astronomy in its scientific form, although of a later date than the "*Syntaxis*" of Ptolemy, is original and not borrowed from foreign source. There is evidence that some crude form of Greek astronomy was transmitted to India and went by the name of the "*Romaka*" or the "*Paulīśa*" Siddhānta, prior to the time of Āryabhaṭa but our great Indian astronomers, Āryabhaṭa with his pupils, Varāha-mihira and Brahmagupta, had to construct a new science altogether.

(This Chapter is almost a reproduction of the paper by P. C. Sengupta, as acknowledged earlier).

CHAPTER VII

Epicyclic Theory of Ancient Indians

We shall give here some details of the Indian concepts regarding the motion of planets or wandering bodies among the stars. The *Vedāṅga Jyotiṣa* (1400 B. C. or earlier) does not speak of this. A comparison of the astronomical constants of the Greek and the ancient Indian systems, points unmistakably to the conclusion that the Indian constants as determined by Āryabhaṭa I and his successors, are almost in all cases different from those of Greeks. Indian astronomers were highly original in their concepts and treatment. The originality of Āryabhaṭa I and other astronomers would be seen from what we are describing below.

Apparent Motions of the Sun and Moon

We have the following passages from Āryabhaṭa :

All planets move in eccentrics to their orbits at the mean rates of angular motion, in the direction of the signs of the zodiac from their apogees (or aphelia) and in the opposite directions from their *Śighroccas*.

The eccentric circles of planets are equal to their concentrics and the centre of the eccentric is removed from the centre of the Earth.

The distance between the centre of the Earth and the centre of the eccentric is equal to the radius of the planet's epicycle; on the circumference (whether of the epicycle or of the eccentric) the planet undoubtedly moves with the mean motion.

Fig. 15

Here the central idea was that undoubtedly planets moved uniformly in circles round the Earth; if the motion appeared to be variable, it was due to the fact that the centres of such circle (i. e. the concentric circles) did not coincide with the centre of the Earth.

Let E represent the centre of the Earth (Fig. 15). APM the Sun's circular orbit or concentric; let A and P be the apogee and the perigee respectively. From EA, cut off EC equal to the radius of the Sun's epicycle. With centre C and radius equal to EA describe the eccentric A'P'S cutting AP and AP produced at P' and A'. Here A' and P' are the real apogee and perigee of the Sun's orbit. Let PM and P'S be any two equal arcs measured from P and P'.

The idea is that the mean planet M and the apparent Sun S move simultaneously from P and P' in the counterclockwise direction along the concentric and the eccentric circles. They move with the same angular motion and arrive simultaneously at M and S.

Here EM and CS are parallel and equal, hence MS is also equal and parallel to EC. Let SH be drawn perpendicular to EM.

The angle PEM is the mean anomaly and the angle P'ES the true anomaly; the angle SEM is the equation of the centre, is readily seen to be plus (+) from P' to A' and minus (-) from A' to P'. Thus as regards the character of the equation, the eccentric circle is quite right. We now turn to examine how far it is true as to the amount.

Let the angle SEM denoted by E and the angle $\angle PEM = \angle P'CS = \theta$; $EP = CP' = a$; $EC = MS = p$, then

$$\tan E = \frac{SH}{HE} = \frac{p \sin \theta}{a - p \cos \theta}$$

$$\therefore E = \frac{p}{a} \sin \theta - \frac{p^2}{2a^2} \sin 2\theta + \frac{p^3}{3a^3} \sin 3\theta \dots\dots\dots$$

Now the true value of E in elliptic motion is given by

$$E = \left(2e - \frac{e^3}{4} \right) \sin \theta + \frac{5}{4} e^2 \sin 2\theta + \frac{13e^3}{12} \sin 3\theta^* \dots$$

If we now put $\frac{p}{a} = 2e - \frac{e^3}{4}$, as a first approximation $\frac{p}{a} = 2e$.

Hence $\frac{p^3}{2a^3} = 2e^3$, which is greater than $\frac{5}{4} e^2$ by $\frac{3}{4} e^2$. In the case of the Sun if the value of p be correctly taken the error in the coefficient of the second term becomes +3'; similarly in the case of the Moon, the corresponding error becomes +8'.

*Godfray's *Astronomy*, p. 149.

Again if $\frac{p}{a}=2e$, what is the centre of the eccentric circle is the empty focus of the ellipse or that the ancient astronomers practically took the planets to be moving with uniform angular motion round the empty focus. This was not a bad approximation.

Also $ES=r=EH$ approximately,

$$\therefore r=a \left(1 - \frac{p}{a} \cos \theta \right)$$

but in the elliptic motion

$$r=a(1-e \cos \theta).$$

Hence the error is not very considerable here also.

This is the way in which the ancient astronomers, both Greek and Hindu, sought to explain the inequalities in the motion of the Sun and the Moon. In the case of the Moon, these astronomers took the coefficient $2e - \frac{e^3}{4} = 300'$ nearly; the modern value is $377'$ nearly. The reason for this has been pointed out to be that the Moon was observed correctly only at times of eclipses. At the eclipses of sygygies, the evection term of the Moon's equation diminishes (numerically) the principal ecliptic term by about $76'$.

We have thus far explained the idea of planetary motion of the ancients under the eccentric circle construction. The same, however, is explained under the epicyclic construction.

Let AMP be the circular orbit of the Sun, having E the centre of the earth for the centre. (Fig. 16)

Let the diameter AEP be the apse line. A the apogee and P the perigee. Let M be the mean position of the Sun in the orbit. With M as the centre, describe the epicycle UNS. Let EM cut the epicycle at N and U. Now the construction for finding S the apparent Sun is thus given:—

Fig. 16

Make $\angle UMS = \angle MEA$, the arc US is measured clockwise whereas the arc A to M is measured counterclockwise.

From this construction MS is parallel to EA. If EC be measured equal to MS, the radius of the epicycle, along EA to—

* Godfray's *Astronomy*, p. 149.

wards the apogee, then CS is a constant length and C is a fixed point. Hence the locus of S is an equal circle with the centre at C . Thus both the eccentric, and the epicycle and the concentric combined, led to the same position.

It was thus usual to explain the planetary motion under both the assumed constructions; and both gave the position for a planet. The eccentric circle construction appears to be the earlier in the history of astronomy and the latter was later. If the former construction can be traced to Apollonius of Perga who did so much to develop the "conic sections" as science, the reason why he preferred the eccentric circle to the ellipse, appears to be that either that this planetary construction was always deep-rooted in the minds of men or that he was carried by the idea that "the circle was the most perfect curve." We are inclined to the view that the eccentric circle idea was transmitted from Babylonia to Greece. We now pass on to consider the Indian construction for the position of superior and inferior planets.

Superior Planets

With regard to the five planets, Mercury, Venus, Mars, Jupiter and Saturn, the Indian astronomers give only one construction for finding the apparent geocentric position. Each of these "star planets" is conceived as having twofold planetary inequalities: (i) the inequality of apsis, (ii) the inequality of the *śighra*. With regard to the superior planets, the *śighra* apogee or the *śighrocca* coincided with the mean position of the Sun. As Varāhamihira observed, of the other planets beginning with Mars, the Sun is the so-called *śighra*. (*PSi*. XVII. 1)

Fig. 17

Let $AMSP$ be the concentric of which the centre E is the same as that of the earth (Fig. 17); $A'M_1P'$ the eccentric circle of apsis of a superior planet, of which the centre is C ; A, M, S, P be respectively the apogee, the Mars planet, the direction of the *śighra* and the perigee of the concentric; A', M_1, P' be the apogee, the planet as corrected by the equation of apsis, P' the perigee in the eccentric. The arc

$AM = \text{arc } A'M_1$; MM_1 is parallel and equal to EC . As used before, both the concentric and the eccentric are of the same radius.

Here the mean planet M in the concentric is taken to be deflected to M_1 due to the true motion in the eccentric circle. Join EM_1 cutting the concentric at M_2 . Now let ES be joined and let S' be taken along ES , such that

$$\begin{aligned} \frac{ES'}{ES} &= \frac{\text{Sighra periphery of the planet in degrees}}{360} \\ &= \frac{\text{Sun's mean distance from the Earth}}{\text{Planets mean distance from the Sun or the Earth;}} \end{aligned}$$

ES' thus determined is called the radius of the *sighra* epicycle of the superior planet.

With S' as the centre and the radius equal to ES or EA describe another circle which is called the *sighra* eccentric cutting ES produced at S'' . Now measure the arc $S''M_2$ in the concentric $= SM_2$ in the concentric. The apparent superior planet is seen in the direction EM_2 from the Earth. This is the construction used in Hindu astronomy calculating the geocentric longitude of any star planet.

It is evident in the case of a superior planet that the eccentric having S' for the centre and whose radius $= EA = R$ the standard radius for any circular orbit, is the mean orbit of the planet and S' the mean position of the Sun. In other words, in the case of a superior planet, the *sighra* eccentric represents the mean orbit round the Sun. If the parallelogram $CES'C'$ be constructed, then an equal circle described with C' as the centre is the apparent eccentric orbit of the superior planet.

In the actual method of calculating the geocentric longitude of a "star planet" there are four operations given, the first two of which have the effect of changing the arc MA or rather the point A . The last two operations relate to the two displacements MM_1 and M_2M_3 . We have here followed solely the construction of the eccentric circles; the same geocentric position of a superior planet could be equally well obtained by the epicyclic construction. In describing the constructions for finding the position, of an inferior planet we shall follow the epicyclic construction only

Inferior Planets

Let E be the centre of the Earth (Fig. 18), AMS the orbit of

a mean inferior planet or the mean Sun. EA the direction of the apogee of apsis and ES that of the *śighra*. The inequality of the apsis takes the mean geocentric planet from M to M_1 , such that MM_1 is parallel to EA. Let EM_1 be joined cutting the concentric at M_2 ; M_2 is taken as the centre of the *śighra* epicycle or the real circular orbit in which the apparent planet moves.

Fig. 18

With M_2 as the centre and the radius of the inferior planets' *śighra* epicycle as radius, describe the circle NVU which is here the *śighra* epicycle or the real circular orbit. In it draw the radius M_2V parallel to ES; then VP is the geocentric position of the inferior planet.

Here the first displacement MM_1 is due to the inequality of apsis and is for finding the position of M , the centre of the real circular orbit. The idea was that the apparent planet moved in a circular orbit of which the centre was very near the mean position of the Sun, the first operation in this construction was calculated to determine the centre of this so-called circular orbit of an inferior planet.

The *śighra* of an inferior planet moves round the Earth at the same mean rate in which the inferior planet moves round the Sun; hence the line ES in this figure is always parallel to the line joining the Sun to the mean heliocentric inferior planet, and in our construction, it is parallel to M_2V .

This in brief is an outline of the Indian idea of planetary motion as taught by Āryabhaṭa I, Brahmagupta and Bhāskara II.

CHAPTER VIII

Brahmagupta and Arithmetic

Scope of Gaṇita

The word *Gaṇita* means the science of calculation. The term occurs in the *Vedāṅga Jyauṭiṣa* (c. 1200 B. C.) :

Just as the crest is to the peacocks, and just as the head-gem is to the snakes, so the *Gaṇita* among the *Vedāṅga Śāstras* stands at the head.¹ (VJ. 4)

In the ancient Buddhistic literature, we find mention of three classes of *gaṇita* : (i) *mudrā* (finger arithmetic), (ii) *gaṇanā* (mental arithmetic), and (iii) *saṃkhyāna* (higher arithmetic in general). In the *Brahmasphuṭasiddhānta*, Brahmagupta uses the word *gaṇita* in the sense of entire calculations. His *gaṇitadhyāya* (Chapter XII) includes :

(i) *Miśra* (mixtures), (ii) *Śreṇhī* (series), (iii) *Kṣetra* (plane figures), (iv) *Uṛtta-kṣetra* (circles), (v) *Khāta* (excavations), (vi) *Citi* (piles of bricks), (vii) *Krākacika* (sawn pieces of timber), (viii) *Rāsi* (heaps or mounds of grain), and (ix) *Chāya* (shadow).

Brahmagupta also uses the term *Dhūlikarma* (literally meaning "aspwork") for higher mathematics :

The one learned man who knows the *dhūlikarma* or the science of mathematics as propounded by Brahmagupta would far excell them in learning who are taught the calculations according to Āryabhaṭa, Viṣṇucandra and others.²

In these ten chapters of the *Brahmasiddhānta* has been given the *dhūlikarma* or the science of entire calculations

1. यथा शिखा मयूराणां नागानां मणयो यथा ।

तद् वद् वेदाङ्ग-शास्त्राणां गणितं मूर्धनि स्थितम् ॥

VJ. 4.

2. नावायौ ज्ञातेरपि तन्त्रैरार्यभट्टविष्णुचन्द्राद्यैः ।

यो ब्रह्म धूलिकर्मविदाचार्यत्वं भवति तस्य ॥

—BrSpSi. X. 62.

which is faultless.¹

This science of *dhulikarma* has not been imparted by great teachers for blasphemy. One who would be using it for this purpose would lose all good name.²

Brahmagupta uses the term *ganita* only for those calculations which are of arithmetical in nature. The science of algebra, the foundations of which was laid by Āryabhaṭa I, was named as *kuttaka* or *kuttākāra* by Āryabhaṭa, and in the *Brāhmasphuṭa-siddhānta* also it is separately dealt with under *Kuṭṭādhyāya* or *kuṭṭakādhāya* (Chapter XVIII). Later on the term *bījaganita* was specifically given to the science of algebra.

The *Kuṭṭādhyāya* of the *Brāhmasphuṭasiddhānta* deals with the (i) concept of *kuttaka* (pulveriser), addition of positive and negative as well as zero quantities, equations in one unknown (*eka-varṇa samikarāṇa*), equations in several unknowns (*aneka-varṇa samikarāṇa*), equations involving products of unknowns (*bhāvita*) and quadratic equations (*varga-prakṛtiḥ*) (Chapter XVIII of the *Brāhmasphuṭasiddhānta*).

Āryabhaṭa, Bhāskara and Brahmagupta use Place Value Notations.

In Europe the first definite traces of the place-value numerals are found in the tenth and eleventh centuries, but the numerals came into general use in mathematical text books only in the seventeenth century. In India, however, Āryabhaṭa I (499), Bhāskara I (522), Lalla (c. 598) and Brahmagupta (628) all use the place value numerals. There is no trace of any other system in their works. Perhaps in this country we had the place value system as early as 200 B.C. if not earlier. The use of a symbol for zero is found in Piṅgala's *Chandaḥ Sūtra* (perhaps of 200 B.C.). In literature, we have an indication of the place value from about 100 B.C. and later in the Purāṇas from the second to the fourth century A.D. The *Bakhasālī Manuscript* (perhaps of 200 A.D.) uses the place-value notations. The earliest use of the place value principle with the letter numerals

1. ग्रहयोगेन ग्रहयुतिरार्योत्रिशतियुताष्टसप्तत्या ।

अध्यायैदेशमिष्टं लिङ्गं योच्चेर्विना ब्रह्म ॥

—BrSpSi. X. 66.

2. गुरुणा न धूलिकर्म प्रतिकंचुककारिणे प्रदातव्यम् ।

यत्तु सुहृत्प्रसादां कुरुते प्रतिकंचुकं यत्न ॥

—BrSpSi. X. 67

is found in the works of Bhāskara I about the beginning of the sixth century A.D. Thus for 3179, the expressive words are *Navādirūpāgni*¹ (*nava* 9, *adri* 7, *rupa* 1 and *agni* 3). Similarly in the *Brāhmasphuṭasiddhānta*, for a large number like 2296828522, the expressive terms are DVIYAMAŚARĀṢṬAPAKṢAVASŪRA-SANAVADVİYAMĀḤ (*Dviyama* two twos 22, *Śara* 5, *aṣṭa* 8, *pakṣa* 2, *vasū* 8, *rasa* 6, *nava* 9, *dviyamāḥ* 22).² Such usages are to be found in all works, which clearly state the place value concept was popular as a routine. From India, this system reached Arabia. During the reign of the Khalif Al-Mansur (753-774 A.D.) there came embassies from Sindh to Baghdad, and among them were scholars, who brought along with them several works on mathematics including the *Brāhmasphuṭasiddhānta* and the *Khaṇḍakhādya* of Brahmagupta. With the help of these scholars, Al-fazari, perhaps also Yakub ibn Tarik, translated them into Arabic. Both works were largely used and exercised great influence on Arab mathematics. It was on that occasion that the Arabs first became acquainted with a scientific system of astronomy. It is acceptable to all writers on the subject that it was at that time that the Hindu numerals were first definitely introduced amongst the Arabs. Arabs at first adopted the *ghobar* form of numerals which they had already obtained (but without zero) from the Alexandrians or from the Syrians. This they continued for about two centuries, but since they were not suited to their right-to-left script, they gave them up and adopted the more convenient ones. For a detailed discussion on how numerals went to the west from India and spread in Europe one is referred to this discussion in the *History of Hindu Mathematics*, Part I by Datta and Singh (1935, Single volume Edition, 1962, pp. 83-104). It is remarkable that Brahmagupta's works like the *Brāhmasphuṭasiddhānta* and the *Khaṇḍakhādya* became instrumental in the spread of the place-value notation in the neighbouring countries of the Middle East, and from their this system spread into Europe.

Operations and Determinations in Pāṭigaṇita

The word *Pāṭigaṇita* is a compound formed from the words *pāṭi*, meaning 'board', and *gaṇita*, meaning 'science of calculation',

1. MBh. 1. 4;

2. BrSpSi 1-16.

hence it means the science of calculation which requires the uses of writing material (the board). The word *pāṭi* is not Sanskrit (it originated in the non-Sanskrit literature in India); the oldest term in Sanskrit for the board is *Phalaka* or *paṭṭa*. However this term got currency in the Sanskrit literature also about the beginning of the seventh century. Brahmagupta does not use the term *pāṭiganita*: he favours the use of the term *dhūlikarma* or writing figures on dust spread on a board or on the ground. The word *pāṭiganita* was translated into Arabic as *ilm-hisab-al-takht* (calculation on board) and the word *dhūlikarma* as *hisab-al-ghobār* (calculation on dust).

Brahmagupta, in the very first verse in the Chapter XII (*Gaṇitādhyāya*) refers to twenty operations (*parikarma*) and eight determinations :

He who distinctly and severally knows the twenty logistics, addition etc., and the eight determinations (*vyavahāra*) including (measurement by) shadow is a *gaṇaka* (mathematician).¹

The commentators have given the list of these logistics (*parikarma*) and determinations* (*vyavahāra*) as follows;

(A) *Parikarma* or logistics

1. Saṁkalitam (addition)
2. Vyavakalitam (subtraction)
3. Gaṇanam (multiplication)
4. Bhāgaḥārah (division)
5. Vargaḥ (square)
6. Vargamūlam (square-root)
7. Ghaṇaḥ (cube)
8. Ghaṇamūlam (cube root)
9. 13. Five standard forms of fractions (Pañca-jāti)
14. Trairāśikam (the rule of three)
15. Vysta-trairāśikam (the inverse rule of three)
16. Pañca-rāśikam (the rule of five)
17. Sapta-rāśikam (the rule of seven)
18. Nava-rāśikam (the rule of nine)

1. परिक्रमं विरिति यः संकलितार्थां पृथक् विजानाति ।

अथैव च व्यवहारान् क्षायान्तान् भवति गणकः सः ॥

19. Ekādaśa-rāśīkam (the rule of eleven)
20. Bhāṇḍa-pratibhāṇḍam (barter and exchange)

(B) *Vyavahāra* or determinations

1. Miśrakāḥ (mixture)
2. Śreṇhī (progression or series)
3. Kṣetram (plane figures)
4. Khātam (excavation)
5. Citih (stock)
6. Krākacikāḥ (saw)
7. Rāśih (mound)
8. Chāyā (shadow)

Of the operations enlisted here, the first eight have been considered fundamental by later writers as Mahāvira. The operations of duplation and mediation (doubling and halving) were considered fundamental by Arabs, Greeks and Egyptians; since they were not familiar with the place-value system.

Mathematics in this country developed as an aid to astronomy, and therefore, for the first time we find Āryabhaṭa (499 A.D.) in his *Āryabhaṭīya* describing as a special section (*Gaṇitapāda*). Brahmagupta (628 A.D.) also followed Āryabhaṭa in this respect and gave the science of calculation (*gaṇita*) a special place in his treatise on astronomy. The *Siddhānta* treatises, earlier than those of Āryabhaṭa and Brahmagupta do not contain a chapter exclusively devoted to *gaṇita* (the *Sūrya-Siddhānta* and the *Siddhāntas* of *Vasiṣṭha*, *Pitāmaha* and *Romaka* are thus without *gaṇita* chapters). Later on Bhāskara I and Lalla also did not include *gaṇita* as a section or chapter in their treatises. It is said, however, that Lalla wrote a separate treatise on *Pāṇiganita*.

It may further be remarked here that Āryabhaṭa I gives the rules for finding the square and cube-roots only whilst Brahmagupta gives the cube-root rule only (*BrSpSi*. XII. 7).

Multiplication

Undoubtedly the common Indian name 'multiplication' is 'gunana', this term occurs in the Vedic literature also. The other terms for this logistics are *hanana*, *radha*, *kṣaya* etc., which all mean 'killing' or 'destroying.' The synonyms of 'hanana' (killing) for multiplication have been used by Āryabhaṭa I (499). Brahmagupta (628), Śrīdhara (c.750) and later writers, and these terms

also occur in the Bakhaśālī Manuscript.

Āryabhaṭa I does not mention the everyday methods of multiplication in his *Āryabhaṭīya* probably because they were too elementary to be included in a Siddhānta work. Brahmagupta, however, in a supplement to the section on mathematics in his *Siddhānta*, gives the names of some methods with very brief descriptions of the processes:—

The multiplicand repeated, as in *gomūtrikā* as often as there are digits in the multiplier, is severally multiplied by them and (the results) added according to places; this gives the product. Or the multiplicand is repeated as many times as there are component parts in the multiplier.¹

(the word *bheda* occurring in the verse has been translated as "integrant portions" by Colebrooke p. 319. Again by the term *bheda* are meant portions which added together make the whole, or aliquot parts which multiplied together make the entire quantity.

The multiplicand is multiplied by the sum or the difference of the multiplier and an assumed quantity and, from the result the product of the assumed quantity and the multiplicand is subtracted or added.²

(Colebrooke thinks that this is a method to obtain the true product when the multiplier has been taken to be too great or too small by mistake.³ Datta and Singh think, however, that this is not correct.⁴

Thus Brahmagupta mentions four methods of multiplication: (i) *gomūtrikā*, (ii) *khaṇḍa*, (iii) *bheda*, and (iv) *iṣṭa*. The common and the well known method of *kapāṭa-sandhi* has been omitted by him.

1. गुणकारखण्डतुल्यो गुण्यो गोमूत्रिकाङ्कतो गुणितः ।

सहितः प्रत्युत्पन्नो गुणकारकमेतदुल्लो वा ॥

—BrSpSi XII. 55

2. गुण्यो राशिगुणकारराशिनेष्टाधिकोनकेन गुणः ।

गुणकोष्टद्वयो न युतो गुणकेऽभ्यधिकोनके कार्यः ॥

—BrSpSi. XII. 56

3. Colebrooke, T. H., *Hindu Algebra*, p. 320.

4. Datta, B. and Singh, A. N., *History of Hindu Mathematics Pt. I (Arithmetic)*, p. 135 (1962).

(i) *Gomūtrika*-method or zig-zag method. The word *gomūtrikā* means "similar to the course of cow's urine", hence "zigzag". This method in all essentials is the same as the *sthāna-khaṇḍa* method. The following illustration is based on the commentary of Pṛthūdaka Svāmī :

Example : To multiply 1223 by 235.

The numbers are written thus :

$$\begin{array}{r} 2 \quad 1223 \\ 3 \quad 1223 \\ 5 \quad 1223 \end{array}$$

The first line of figures is then multiplied by 2, the process beginning at units place, thus : $2 \times 3 = 6$; 3 is rubbed out and 6 substituted in its place, and so on. After all the horizontal lines have been multiplied by the corresponding numbers on the left in the vertical line, the numbers on the *pāṇi* stand thus :

$$\begin{array}{r} 2446 \\ 3669 \\ 6115 \\ \hline 287405 \end{array}$$

after being added together as in the present method.

The *sthāna-khaṇḍa* and the *gomūtrikā* methods resemble modern plan of multiplication most closely.

(ii) *Khaṇḍa* Method or Parts Multiplication Method : Since the days of Brahmagupta, this method of multiplication also became very popular. We have two methods under this head :

(i) The multiplier is broken up into two or more parts whose sum is equal to it. The multiplicand is then multiplied severally by these and the results added.

To take an example :

$$\begin{aligned} 13 \times 158 &= (6+7) \times 158 = (6 \times 158) + (7 \times 158) \\ &= 948 + 1106 \\ &= 2054 \end{aligned}$$

(ii) The multiplier is broken up into two or more aliquot parts. The multiplicand is then multiplied by one of these, the resulting product by the second and so on till all the parts are exhausted. The ultimate product is the result.

Thus for example :

$$\begin{aligned} 96 \times 237 &= (4 \times 4 \times 6) \times 237 \\ &= (4 \times 237) \times 4 \times 6 = 948 \times 4 \times 6 \\ &= (4 \times 948) \times 6 = 3792 \times 6 \\ &= 22752 \end{aligned}$$

These methods of multiplication are found among the Arabs and the Italians, having obtained from people of India. They were known as the "Scapezzo" and "Repiego" methods respectively amongst Italians.

(iii) *Iṣṭa-guṇana* Method or the Algebraic Method.

We have already quoted the relevant verse from the *Brahmasphuṭa-siddhānta* in this connection; (XII. 56) :

The multiplicand is multiplied by the sum or the difference of the multiplier and an assumed quantity and from the result the product of the assumed quantity and the multiplier is subtracted or added.¹

This method is of two kinds according as we (i) add or (b) subtract an assumed number. The assumed number is so chosen as to give two numbers with which multiplication will be easier than with the original multiplier. The two ways are illustrated below :

$$(i) 93 \times 13 = (93 + 7) \times 13 - 7 \times 13 = 1300 - 91 = 1209.$$

$$(ii) 93 \times 13 = (90 + 3) \times 13 = 90 \times 13 + 3 \times 13 = 1170 + 39 = 1209$$

This method was in use among the Arabs and in Europe, obviously having gone out from this country.

This process has been regarded as an inverse of multiplication. The terms used for this operation are *bhāgahāra*, *bhājana*, *harana*, *chedana*, etc., all these terms more or less carrying the sense "to break into parts", "to divide" etc., excepting "*harana*" which denotes "to take away". This term shows the relation of division to the operation of subtraction. The dividend is termed as *bhājya*, *hārya* etc., the divisor is known as

1. गुरुको राशिगुणकारराशिनेष्टाधिकोनकेन गुणः ।

कुम्भेष्टवो न युतो गुणकेऽभ्यधिकोनके कार्यः ॥

bhājaka, *bhāgaḥara* or simply *hara*; quotient is known as *labdhi* or *labdha* (or “what is obtained”).

India never regarded this operation as a difficult one; in Europe, this operation was regarded as a tedious one till the 15th century or so. Division was such a common operation that Āryabhaṭa did not regard it as worth being included in his treatise. But since he has given the methods of extracting square-roots and cube-roots, which obviously depend on division, we conclude that the method of division was known to him. Most *Siddhanta* writers have followed Āryabhaṭa I in omitting this operation from their texts, this being regarded too elementary to be included. Brahmagupta does not give details of this operation. The later treatises on Arithmetic as Śrīdhara's *Trisatikā* and the *Pāṇiganita* (I.20) and Āryabhaṭa II (c.950 A.D.) have given the details of this operation.

Square

The Sanskrit term for square is *varga* or *kṛti* (*varga* literally means “rows” or “troops” of similar things). In mathematics, it usually means the square power and also the square figure or its area. Thus we find in the *Āryabhaṭīya* :

A square figure of four equal sides (and the number representing its area) are called *varga*. The product of the two equal quantities is also *varga*¹.

The term *kṛti* means “doing”, “making” or “action”. It carries with it the idea of specific performance probably the graphical representation.

For the first time we have a definite rule for squaring in the writings of Brahmagupta. But it does not mean that prior to him it was not known. It must have been known to Āryabhaṭa I since he has given the square-root method.

Brahmagupta gives his method of squaring briefly as follows :

Combining the product, twice the digit in the less (lowest) place into the several others (digits) with its (i.e. of the digit in the lowest place) square (repeatedly) gives the square.²

1. वर्गस्तमन्तुरश्रः फलञ्च सदृशद्वयस्य संवर्गः ।

2. राशेरूनं द्विगुणं बहुतरगुणमनकृतियुतं वर्गः ।

—Ārya. II. 3.

—BrSpSi. XII. 63.

The method has been more clearly enunciated by Mahāvīra (850 A.D.) in the *Gaṇitasārasaṃgraha* :

Having squared the last (digit), multiply the rest by the digits by twice the last, (which) is moved forward (by one place). Then moving the remaining digits continue the same operation (process), This gives the square.¹

Brahmagupta's method of squaring is shown by the following example :

To square 125.

The number is written down

125

The square of the digit in the last place, i. e., $5^2=25$ is set over it thus :

25

125

Then, $2 \times 5=10$ is placed below the other digits, and 5 is rubbed out, thus :

25

12

10

Multiplying by 10 the rest of the digits, i.e., 12 and setting the product over them (the digits), we have.

1225

12

10

Then rubbing out 10 which is not required and moving the rest of the digits, i. e. 12 we, have

1225

12

Thus one round of operations is completed.

Again as before, setting the square of 2 above it and $2 \times 2=4$ below 1, we have

1625

1

4

1. GSS. P. 12.

Multiplying the remaining digit 1 by 4, and setting the product above it, we have

$$\begin{array}{r} 5625 \\ 1 \end{array}$$

Then moving the remaining digit 1, we obtain

$$\begin{array}{r} 5625 \\ 1 \end{array}$$

Thus the second round of operations is completed.

Next setting the square of 1 above it the process is completed for there are no remaining figures, and the result stands thus :

$$15625$$

Algebraic Method of Squaring

Brahmagupta in his *Brāhmasphuṭasiddhānta* gives a minor method of squaring thus :

The product of the sum and the difference of the number (to be squared) and an assumed number plus the square of the assumed number give square¹.

This may be represented by the following identity :

$$n^2 = (n-a)(n+a) + a^2$$

This identity has been used for squaring by most of the Indian mathematicians. Thus

$$15^2 = (15-5)(15+5) + 5^2 = 225$$

We are not giving here other identities which have been used by latter mathematicians of India in getting the squares of numbers; for example, when Mahāvīra says :

The sum of the squares of the two or more portions of the number together with their products each with the others multiplied by two gives the square² :

he obviously refers to the identity

$$(a+b+c+\dots)^2 = a^2 + b^2 + c^2 + \dots + 2ab + \dots$$

Cube

The Sanskrit term for cube is *ghana*. It when used in the geometrical sense also means the solid cube. In the arithmetical sense, it means the continued product of the same number taken three times. Thus we have the definition in the *Ārya-*

1. राशेरिष्टयुतोनाद्वयः कृतिर्वैकृतियुक्तः ।

2. GSS. p. 13.

bhaṭṭya :

The continued product of three equals and also the solid having twelve (equal) edges are called *ghana*.¹

A method of cubing applicable to numbers written in the decimal place-value notation, has been in use in this country from before the 5th century A.D. Āryabhaṭa I (499 A.D.) had the familiarity with this method; he, however, does not give the method of cubing in his treatise, though he describes the inverse process of extracting the cube-root.

Brahmagupta gives the method of cubing in the following verse :

Set down the cube of the last (*antya*); then place at the next place from it, thrice the square of the last multiplied by the succeeding; then place at the next place thrice the square of the succeeding multiplied by the last, and (at the next place) the cube of the succeeding. This gives the cube.²

The rule may be illustrated by an example.

Example : To cube 1357.

The given number has four places, i.e., four portions. First we take the last digit 1 and the succeeding digit 3, i.e. 13 and apply the method of cubing thus :

- | | |
|---|----------------------------------|
| (i) Cube of the last (1^3) | = 1 |
| (ii) Thrice the square of the last (3.1^2) multiplied by the succeeding (3) gives ($3.3.1^2$) | = 9 (placing at the next place) |
| (iii) Thrice the square of the succeeding, multiplied by the last gives ($3.3^2.1$) | = 27 (placing at the next place) |
| (iv) Cube of the succeeding (3^3) | = 27 (placing at the next place) |

Thus 13^3 is the sum

2197

1. सदृशवर्गसंघो घनस्तथा द्वादशामस्यात् ॥

—Ārya, II. 3.

2. स्थानोन्वयान्नोन्वयकृतिस्त्रिगुणोत्तरसंगुणा च तत्प्रथमान् ।

उत्तरकृतिरन्वयगुणा त्रिगुणा चोत्तर घनश्च घनः ।

—BrSpSi. XII, 6.

bhaṭṭya :

The continued product of three equals and also the solid having twelve (equal) edges are called *ghana*.¹

A method of cubing applicable to numbers written in the decimal place-value notation, has been in use in this country from before the 5th century A.D. Āryabhaṭa I (499 A.D.) had the familiarity with this method; he, however, does not give the method of cubing in his treatise, though he describes the inverse process of extracting the cube-root.

Brahmagupta gives the method of cubing in the following verse :

Set down the cube of the last (*antya*); then place at the next place from it, thrice the square of the last multiplied by the succeeding; then place at the next place thrice the square of the succeeding multiplied by the last, and (at the next place) the cube of the succeeding. This gives the cube.²

The rule may be illustrated by an example.

Example : To cube 1357.

The given number has four places, i.e., four portions. First we take the last digit 1 and the succeeding digit 3, i.e. 13 and apply the method of cubing thus :

- | | |
|---|----------------------------------|
| (i) Cube of the last (1^3) | = 1 |
| (ii) Thrice the square of the last ($3 \cdot 1^2$) multiplied by the succeeding (3) gives ($3 \cdot 3 \cdot 1^2$) | = 9 (placing at the next place) |
| (iii) Thrice the square of the succeeding, multiplied by the last gives ($3 \cdot 3^2 \cdot 1$) | = 27 (placing at the next place) |
| (iv) Cube of the succeeding (3^3) | = 27 (placing at the next place) |

Thus 13^3 is the sum

2197

1. सप्तशतसंकोषे वनस्तथा द्वादशामस्यात् ॥

—Ārya, II. 3.

2. स्वायोन्यधनोन्यकृतिस्त्रिगुणोत्तरसंगुणा च तत्प्रथमान् ।

उत्तरकृतिर्न्यगुणा त्रिगुणा चोत्तर वनश्च वनः ।

—BrSPSi. XII, 6.

After this we take the next figure, 5, i.e., the number 135, and in this consider 13 as the last and 5 as the succeeding. Then the method proceeds thus :

- (i) The cube of the last
(13³) as already obtained = 2197
- (ii) Thrice the square of the
last multiplied by the
succeeding, i.e. $3 \cdot 13^2 \cdot 5$ = 2595 (placing at the
next place)
- (iii) Thrice the square of the
succeeding multiplied
by the last, i.e. $3 \cdot 5^2 \cdot 13$ = 975 (placing at the
next place)
- (iv) Cube of the succeeding,
i.e. 5^3 = 125 (placing at the
next place)

Thus 135^3 is the sum 2460375

Now the remaining figure 7 is taken, so that the number is 1357, of which 135 is the last and 7 the succeeding. The method proceeds thus :

- (i) Cube of the last, i.e.
(135³) as already
obtained = 2460375
- (ii) Thrice the square of
the last into the succee-
ding, i.e. $3 \cdot (135)^2 \cdot 7$ = 382725 (placing at the
next place)
- (iii) Thrice the square of
the succeeding into the
last, i.e. $3 \cdot 7^2 \cdot 135$ = 19845 (placing at the
next place)
- (iv) Cube of the succeeding
i.e. 7^3 = 343 (placing at the
next place)

Thus $(1357)^3$ is the sum 2498846293

Evidently these methods of cubing are based on the identity:

$$(a+b)^3 = a^3 + 3a^2b + 3ab^2 + b^3$$

and keeping in mind the place values of numerals in a given

number (this accounts for keeping the results of each of the four operations at the next place).

Square-Root

Indian synonyms for square-root are *vargamūla* or *pada* of a *kṛti*. The word *mūla* means the "root" of a tree, which may also mean the "foot" or the lowest part or bottom of a thing and hence "pada" or foot also became a synonym of root. Brahmagupta defines square-root as follows :

The *pada* (root) of a *kṛti* (square) is that of which it is the square.¹

While the word *mūla* for root is the oldest in Indian literature (it occurs in *Anuyogadvāra-sūtra*, c. 100 B.C.), the word *pada* for root probably for the first time occurs in the writings of Brahmagupta. The term *mūla* was borrowed by the Arabs who translated it by *jadr*, meaning "basis of square". The Latin term *radix* also is a translation of the term *mūla*. In the Śulba literature and in the Prākṛta texts, we find a term *karaṇi* for square-root. In geometry, this term *karaṇi* means a "side". In later days, the term *karaṇi* was reserved for surds, i.e. a square-root which cannot be exactly evaluated, but which may be represented by a line.

We would like to quote here a rule for determining square-root of numbers from the *Āryabhaṭīya* :

Always divide the even place by twice the square-root (upon the preceding odd place); after having subtracted from the odd place the square (of the quotient), the quotient put down at the next place (in the line of the root) gives the root².

As an illustration, we shall proceed to find the square-root of 18225.

The odd and even places are marked out by vertical (I) and horizontal (—) lines : The other steps are as follows :

1. पदं कृतिर्वत् तत्

BrSpSi. XVIII. 35

2. मासं हरेदकार्गन्तित्वं द्विगुणेन कार्गमूलेन ।
कार्गद्वर्गे शुद्धे लब्धं स्थानान्तरे सूत्रम् ॥

— Ārya, II. 4.

	1 - 1 - 1	
	18225	
Subtract square	1	root = 1
Divide by twice the root	<u>2) 8 (3</u>	placing quotient at the next place, the root=13
	6	
	<u>22</u>	
Subtract square of quotient	9	
Divide by twice the root	26)132(5	placing quotient at the next place, the root=135
Subtract square of the quotient	<u>130</u>	
	25	
	<u>25</u>	

The process ends. The square-root of 18225 is thus 135.

It has been stated by Kaye, that Āryabhata's method of finding out the square-root is algebraic in character, and that it resembles the method given by Theon of Alexandria. Āryabhata's method is purely arithmetic and not algebraic is the view of Datta and Singh who do not agree with Kaye on this point.

Cube Root

The Sanskrit term for cube-root is *ghanamūla* or *ghanapada*. The first mention of the operation of cube-root is found in the *Āryabhaṭya* of Āryabhata I (499 A.D.), though the operation is given in only a concise form :

Divide the second *aghana* place by thrice the square of the cube-root; subtract from the first *aghana* place the square of the quotient multiplied by thrice the preceding (cube-root); and (subtract) the cube (of the quotient) from the *ghana* place; (the quotient put down) at the next place (in the line of the root) gives (the root).¹

As has been explained by all the commentators on the *Āryabhaṭya*, the units place is *ghana*; the tens place is first *aghana*, the hundreds place is the second *aghana*, the thousands place is *ghana*, the ten thousands place is first *aghana*, the hun-

1. अघनाद् भजेद् द्वितीयात् त्रिगुणेन घनस्य मूलवर्गेण ।

वर्गस्त्रिपूर्वं गुणितश्शोध्यः प्रथमाद् घनस्य घनात् ॥

dred-thousands place is second *aghana*, and so on. Thus to find out the cube-root, one has to mark out the *ghana*, first *aghana* and second *aghana* places, then the process of finding out the cube-root begins with the subtraction of the greatest cube number from the figures up to the last *ghana* place. Though this has not been explicitly mentioned in the rule, the commentators say that it is implied in the expression *ghanasya mula-vargena* etc. ("by the square of the cube-root etc.")

We are reproducing here an illustration given by Datta and Singh.

Example. Find the cube-root of 1953125.

The places are divided into groups of three by marking them as below [*ghana* (|) first *aghana* (—) and second *aghana* (—)]:

	— — — —	
	1 9 5 3 1 2 5	
Subtract cube	<u>1</u>	(c) Root=1
Divide by thrice		
square of root,		
i.e. 3.1^2	3)9(2 ...	(a) Placing quotient
Subtract square	<u>6</u>	after the root 1
of quotient mul-	35	gives the root 12
tiplied by thrice	<u>12</u> ...	(b)
the previous root,		
i.e. $2^2.3.1$		
Subtract cube of	233	
quotient, i.e. 2^3	8 ...	(c)
Divide by thrice		
square of the root,		
i.e. 3.12^2	432)2251(5 ...	(a) Placing quotient
Subtract square of	<u>2160</u>	after the root
quotient multiplied		12 gives the
by thrice the pre-	912	root 125
vious root, i. e.		
$5^2.3.12$	<u>900</u>	
Subtract cube of	<u>125</u>	... (b)
quotient, i.e. 5^3	<u>125</u>	... (c)
Thus the cube-root=125.		

From the details given, it would be clear that the present

method of extracting the cube-root is almost a contraction of the method first given by Āryabhaṭa I (499 A.D.)

The method of Āryabhaṭa has been invariably followed by Indian mathematicians. Brahmagupta in his *Brāhmasphuṭa-siddhānta* repeats the method in the following words :

The divisor for the second *aghana* place is thrice the square of the cube-root; the square of the quotient multiplied by three and the preceeding (root) must be subtracted from the next (*aghana* place to the right). and the cube (of the quotient) from the *ghana* place (the procedure repeated gives) the root.¹

Śrīdhara and Āryabhaṭa II have further improved on the method of extracting cube-root proposed by Āryabhaṭa I and followed by Brahmagupta. Rule for finding the cube-root as given by Śrīdhara in his *Paṭīganita* is as follows :

(Divide the digits beginning with the units' place into periods of) one *ghana-pada* (one "cube" place) and two *aghana-pada*s (two "non-cube" places). Then subtracting the (greatest possible) cube from the (last) *ghana-pada* and placing the (cube) root underneath the third place (to the right of the last *ghana-pada*), divide out the remainder up to one place less (than that occupied by the cube root) by thrice the square of the cube-root, which, is not destroyed. Setting down the quotient (obtained from division) in the line (of the cube-root), (and designating the quotient as the 'first' (*ādima*) and the cube-root as the 'last' (*antya*), subtract the square of that quotient, as multiplied by thrice the 'last' (*antya*) from one place less than that occupied by the quotient (*uparima-rāśi*) as before, and the cube of the 'first' (*ādima*) from its own place.

(The number now standing in the line of cube-root is the cube-root of the given number up to its last-but one *ghana-pada* (cube place) from the left).

Again apply the rule, "(placing cube-root) under the third place" etc. (provided there be more than two *ghana-padas* (cube places) in the given number; and

1. छेदो घनाद् द्वितीयाद् घनमूलकृतिस्त्रिसंख्यात्कृतिः ।

शोध्य विपूर्वगुणिता प्रथमाद् घनतो घनो मूलम् ॥

—BrSpSi. XII. 7

continue the process till all *ghana-padas* (cube-places) are exhausted). This will give the (cube) root (of the given number).¹

K.S. Shukla in his translation and commentary of this book has given the illustration of extracting cube-root as follows :

Example :- To find the cube root of 277167808.

Let us indicate *ghana-padas* or 'cube' places by "c" and *aghana-padas* or non-cube places as "n" :

n n c n n c n n c
2 7 7 1 6 7 8 0 8

Subtract the greatest possible cube (i.e. 6^3 or 216) from the last 'cube' place (i.e. from 277) and place the cube-root (i.e. 6) underneath the third place to the right of the last 'cube' place; thus we have

n n c n n c n n c
6 1 1 6 7 8 0 8 (remainder)
6 (line of cube-root)

Dividing out by thrice the square of the cube-root (i.e. by $3 \cdot 6^2$ or 108) the remainder up to one place less than that occupied by the cube-root (i.e. 611) and setting down the quotient in the line of the cube-root (to the right of the cube-root), we have

n n c n n c n n c
7 1 6 7 8 0 8 (remainder)
6 5 (line of cube-root)

Let now quotient 5 be called the 'first' (*ādima*) and the cube-root 6 the 'last' (*antya*). Then subtracting the square of the 'first' (*ādima*) as multiplied by thrice the 'last' (*antya*) (i.e. $3 \times 6 \times 5^2$ or 450) from one place less than that occupied by the quotient (i.e. from 716), we get

1. घनपदमघनपदे द्वे घन (पद) तोऽपास्य घनमदो मूलम् ।

संयोज्य तृतीयपदस्याधस्तदनष्टकं ॥ २६ ॥

एकस्थानोनतया शेषं त्रिगुणेन (सं) भजेत्तत्मात्र ।

सर्वं निवेश्य परं कुर्यात् तद्वर्गं त्रिगुणमन्यहतम् ॥ ३० ॥

बह्व्यस्तुपरिसराशोः प्राप्तवद् घनमादिमस्य (च) स्वपदात् ।

भूयस्तृतीय पदस्याध इत्यादिकं विधिर्भूतम् ॥ ३१ ॥

$$n \ n \ c \ n \ n \ c \ n \ n \ c$$

$$2 \ 6 \ 6 \ 7 \ 8 \ 0 \ 8 \quad \text{(remainder)}$$

$$6 \ 5 \quad \text{(line of cube-root)}$$

And subtracting the cube of the 'first' (*adima*) (i.e. 5^3 or 125) from its own place (i.e. from 2667), we get

$$n \ n \ c \ n \ n \ c \ n \ n \ c$$

$$2 \ 5 \ 4 \ 2 \ 8 \ 0 \ 8 \quad \text{(remainder)}$$

$$6 \ 5 \quad \text{(line of cube-root)}$$

One round of the operation is now over; and the number 65 standing in the line of the cube-root is the cube-root of the given number (277167808) up to its last-but-one 'cube' place (*ghana pada*) from the left (i.e. of 277167),

As there is one more 'cube' place (*ghana-pada*) on the right, the process is repeated. Thus placing the cube-root (i.e. 65) under the third place beginning with the last-but-one 'cube' place (*ghana-pada*), we have

$$n \ n \ c \ n \ n \ c \ n \ n \ c$$

$$2 \ 5 \ 4 \ 2 \ 8 \ 0 \ 8 \quad \text{(remainder)}$$

$$6 \ 5 \quad \text{(line of cube-root)}$$

Dividing out 25428 by $3 \cdot 65^2 (=12675)$ as before, and placing the quotient in the line of the cube-root, we have

$$n \ n \ c \ n \ n \ c \ n \ n \ c$$

$$7 \ 8 \ 0 \ 8 \quad \text{(remainder)}$$

$$6 \ 5 \ 2 \quad \text{(line of cube-root)}$$

Subtracting $3 \times 65 \times 2^3 (=780)$ we get.

$$n \ n \ c \ n \ n \ c \ n \ n \ c$$

$$8 \quad \text{(remainder)}$$

$$6 \ 5 \ 2 \quad \text{(line of cube-root)}$$

Finally subtracting $2^3=8$ from 8, we get

$$n \ n \ c \ n \ n \ c \ n \ n \ c$$

$$0 \quad \text{(remainder)}$$

$$6 \ 5 \ 2 \quad \text{(line of cube-root)}$$

The second round of operation is now over. There being no more of *ghana-pada* ('cube' place) on the right, the process ends. The quantity in the line of cube root, viz., 652, is the cube-root of the given

number. The remainder being zero, the cube-root is exact.

Fractions

The concept of fractions in India can be traced to very early times. In the *R̥gveda*,¹ we find such terms as one-half (*ardha*) and three-fourths (*tri-pāda*). In a passage of the *Maitrayaṇi Samhitā*² are mentioned the fractions one-sixteenth (*kalā*), one-twelfth (*kuṣṭha*), one-eighth (*śapha*) and one-fourth (*pādā*). In the *Śulba Sūtras*³ we have not only a mention of fractions, but they have been used in the statement and solution of problems of geometric nature. Here in the *Śulba*, unit fractions are denoted by the use of cardinal number with the term *bhāga* or *aṁśa*; thus *pañca-dāśa-bhāga* (literally "fifteen parts") is equivalent to one-fifteenth, *sapta-bhāga* (literally, "seven parts") is equivalent to one-seventh, and so on... The use of ordinal numbers with the term *bhāga* or *aṁśa* is also quite common: thus *pañcama bhāga* stands for one-fifth. The composite fractions like *tri-aṣṭama* stands for three-eighths and *dvi-saptama* for two-sevenths. In the *Bakhasālī Manuscript*, the term *tryaṣṭa* occurs for $3/8$ and $3\frac{3}{8}$ is called *trayastrayasta* (three-three-eighths).

The Sanskrit term for fraction is *bhinna* (literally meaning 'broken'). Obviously the European terms as *fractio*, *fraction*, *roupt*, *rotto* or *rocto* are translations of the same term; they are derived from the Latin *fractus* (*frangere*) or *ruptus* meaning 'broken'. The Indian term *bhinna* has a few more connotations; it stands for such numbers of the form :

$$\left(\frac{a}{b} \pm \frac{c}{d}\right), \left(\frac{a}{b} \text{ of } \frac{c}{d}\right), \left(\frac{a}{b} \pm \frac{c}{d} \text{ of } \frac{a}{b}\right) \text{ or } \left(a \pm \frac{b}{c}\right).$$

These forms were termed *jāti* i.e., 'classes', and the Indian treatises contain special rules for their reduction to proper fractions. Śrīdhara and Mahāvīra each enumerate six *jāti*s, while our author, Brahmagupta, gives only five (Bhāskara II gives only four). The need for division of fractions in 'classes' arose out of the lack of proper symbolism to indicate mathematical operations. (Datta and Singh *Arithmetic*, p. 188). The only operational symbol in use was a dot, standing for the negative sign.

1. *Rv.* X, 90,4

2. *Mait S.* III, 7,7.

3. B. Datta, *Śulba*, pp. 212ff.

Reduction to lowest terms.—A non-mathematical work, *Tattvārthadhigama-Sūtra-Bhāṣya* by Umāsvatī (c.150 A.D.) casually mentions as follows in the context of a philosophic discourse:

Or, as when the expert mathematician, for the purpose of simplifying operations, removes common factors from the numerator and denominator of a fraction, there is no change in the value of the fraction, so...¹

Reduction to common denominator. Whenever we have to add or subtract fractions, we follow this reduction operation to a common denominator. Brahmagupta gives the reduction along with the similar processes :

By the multiplication of the numerator and denominator of each of the (fractional) quantities by other denominators, the quantities are reduced to a common denominator. In addition, the numerators are united, In subtraction their difference is taken.²

Fractions in combination :—Since there was no proper symbolism available to these early Indian mathematicians, they divided combination of fractions into four classes :

Bhāga, prabhāga, bhāgapavāha and bhāga-bhāga.

(i) *Bhāga* has been mentioned by Brahmagupta (BrSpSi.

XII. 8) thus : $\left(\frac{a}{b} \pm \frac{c}{d} \pm \frac{e}{f} \pm \dots \right)$ usually written as

$$\left[\begin{array}{c|c|c} a & c & e \\ b & d & f \end{array} \right] \text{ or } \left[\begin{array}{c|c|c} a & .c & .e \\ b & d & f \end{array} \right]$$

where the dots denote subtraction.

(ii) *Prabhāga* : The form $\left(\frac{a}{b} \text{ of } \frac{c}{d} \text{ of } \frac{e}{f} \dots \right)$

This is written as

$$\left[\begin{array}{c|c|c} a & c & e \\ b & d & f \end{array} \right]$$

(iii) *Bhāganubandha* : The form $\left(a + \frac{b}{c} \right)$ is written as

$$\left[\begin{array}{c} a \\ b \\ c \end{array} \right]$$

1. II, 52.

2. विपरीतच्छेदशुल्काः राशयोश्चेदांशकाः समच्छेदाः ।

संकलितेऽपि योज्या व्यवकलितेऽन्तरं कार्यम् ॥

—BrSpSi. XII. 2.

and the form

$$\frac{p}{q} + \frac{r}{s} \text{ of } \frac{p}{q} + \frac{t}{u} \text{ of } \left(\frac{p}{q} + \frac{r}{s} \text{ of } \frac{p}{q} \right) + \dots\dots\dots$$

is written as

$$\left[\begin{array}{c} p \\ q \\ \hline r \\ s \\ \hline t \\ u \end{array} \right]$$

(iv) *Bhāgāpavāha*, i.e., the form $\left(a - \frac{b}{c} \right)$ is written as

$$\left[\begin{array}{c} a \\ b \\ c \end{array} \right]$$

and the form $\frac{p}{q} - \frac{r}{s} \text{ of } \frac{p}{q} - \frac{t}{u} \text{ of } \left(\frac{p}{q} - \frac{r}{s} \text{ of } \frac{p}{q} \right) - \dots\dots\dots$

is written as

$$\left[\begin{array}{c} p \\ q \\ \hline .r \\ s \\ \hline .t \\ u \end{array} \right]$$

(v) *Bhāga-bhāga* : The form

$$\left(a \div \frac{b}{c} \right) \text{ or } \left(\frac{p}{q} \div \frac{r}{s} \right)$$

There does not appear to have been any notation for division, such compounds being written as

$$\left[\begin{array}{c} a \\ b \\ c \end{array} \right] \text{ or } \left[\begin{array}{c} p \\ q \\ \hline r \\ s \end{array} \right]$$

just as for *bhāganubandha*. That division is to be performed was known from the problem, e.g., $1 \div \frac{1}{2}$ was written as *ṣaḍ-bhāga-bhāga*, i.e., "one-sixth *bhāga-bhāga*" or "one divided by one-sixth". It is only in the *Bakhṣālī Manuscript* that the term *bhā* is sometimes placed before or after the quantity affected.

(vi) *Bhāga-mātr*, i.e., combinations of forms enumerated above. Mahāvira, the author of the *Gaṇitasārasaṃgraha* (850

A.D.) gives twenty-six variations of this class. We shall illustrate it by the following example from Śrīdhara :

What is the result when half, one-fourth of one-fourth, one divided by one-third, half-plus half of itself, and one-third diminished by half of itself, are added together ? (*Trisatika*, p. 12).

A modern writer would have written it as :

$$\frac{1}{2} + (\frac{1}{4} \text{ of } \frac{1}{4}) + (1 \div \frac{1}{3}) + (\frac{1}{2} + \frac{1}{2} \text{ of } \frac{1}{2}) (\frac{1}{3} - \frac{1}{2} \text{ of } \frac{1}{3})$$

In the old Indian notation, it is written as

1	1	1	1	1	1
2	4	4	1	2	3
			3	1	1
				2	2
				2	2

The defect of the notation is obvious: $\begin{bmatrix} 1 & 1 \\ 4 & 4 \end{bmatrix}$ can be read

also as $\frac{1}{4} + \frac{1}{4}$ and $\begin{bmatrix} 1 \\ 1 \\ 3 \end{bmatrix}$ can also be read as $1\frac{1}{3}$.

And therefore the original meaning is inferred from the context or from the enunciation of the problem.

The rules for reduction of the first two classes (*bhāga* and *prabhāga*) are those of addition or subtraction and multiplication. The rule for the reduction of the third (*bhāganubandha*) and fourth (*bhāgapavāha*) classes are given by Brahmagupta in the *Brāhmasphuṭa-siddhānta* thus :

The (upper) denominator is multiplied by the denominator and the upper numerator by the same (denominator) increased or diminished by its own numerator.¹

"Numerator" is known as "*aṁśa*" and the "denominator" as "*cheda*."

We give here from Śrīdhara's *Paṭiganīṭa* (about 900 A.D., according to K.S. Shukla, 750 A.D. according to Datta and Singh) a rule for reducing a fraction of the *bhāganubandha* class (i.e., a whole number increased by a fraction or a fraction increased by a fraction itself) :

1. ऊर्ध्वं शारद्धेदगुणास्तृतीयजातौ द्वयोः पृथक्परयोः ।
 द्वेदशब्देदा गुणितः स्वशायुतो नैरुपरिमांशतः ॥

—*BrSpSi. XII. 9.*

In the *bhāganubandha* class, the whole number (*rūpa-gaṇa*) is multiplied by the denominator (of the fraction) should be increased by the numerator (of the fraction) or the upper denominator having been multiplied by the lower denominator, the initial numerator (i.e. the upper numerator) should be multiplied by the sum of the lower numerator and denominator.¹

(*Paṭṅganīta*, 39 cf. *BrSpSi*. XII. 9 (ii); *GSS*. (iii) 113

This means that

$$(i) \quad a + \frac{b}{c} = \frac{ac+b}{c}$$

$$(ii) \quad \frac{a}{b} + \frac{c}{d} \text{ of } \frac{a}{b} \text{ (which was written by Indians in the style}$$

$$\boxed{\frac{\frac{a}{b}}{\frac{c}{d}}}$$

$$\text{is equal to } \frac{a(d+c)}{bd}$$

Addition and Subtraction of Fractions

In the *Brāhmasphuṭa-siddhānta*, Brahmagupta gives the rule for the addition and subtraction of fractions :

If the denominators (*cheda*) of fractions are different then reduce these fractions to a common denominator. Now for the additions, unite the numerators and take their difference in case of subtraction.²

Brahmagupta and Mahāvīra give the method under *Bhāga-jāti*.

Multiplication

Brahmagupta says :

The product of the numerators divided by the pro-

1. भगानुबन्धजतौ रूपगणशब्दे सह गुणः साराः ।

अवरहरणोर्व्यं हरेऽर्धोराऽयुतहरण आगंशः ॥

—*Paṭṅganīta* 39.

2. विपरीतच्छेदगुणाः रास्योश्चेदांशकाः समच्छेदाः ।

संक्रवितेऽशा योज्या व्यवकलितेऽरान्तरं कीर्यम् ॥

—*BrSpSi*. XII. 2

duct of the denominators is the (result of) multiplication of two or more fractions.¹

While all other writers give the rule in the same way as Brahmagupta, Mahāvira in the *Gaṇitasārasaṃgraha* refers to cross reduction in order to shorten the work :

In the multiplication of fractions, the numerators are to be multiplied by the numerators and the denominators by denominators, after carrying out the process of cross reduction, if that be possible.²

Division of Fractions

The *Āryabhaṭīya* does not explicitly give the rule of division, but under the Rule of Three, we have an indication of this operation. The Rule of Three states the result as $\frac{f \times i}{p}$, where f stands for *phala* i.e. "fruit", i for *icchā*, i.e., demand or requisition, and p for *pramāṇa* i.e. argument. When these quantities are fractional, we get an expression of the form

$$\frac{\frac{a}{b} \times \frac{c}{d}}{\frac{m}{n}}$$

for the evaluation of which *Āryabhaṭa* I states :

The multipliers and the divisor are multiplied by the denominators of each other.

These quantities are written in the following way

a	m
b	n
c	
d	

Transferring the denominators we have

a	m
n	b
c	d

Performing multiplication, the result is $\frac{anc}{mbd}$. The above interpretation of the obscure line in the *Āryabhaṭīya* is based

1. रूपान्तरितं गुणान्तरितानि द्वयोर्वहना वा ।

प्रत्युत्पन्नो भवति च्छेदकवेनोदकतोऽरावधः ॥

2. GSS. p. 25. (2)

on the commentaries of Sūryadeva and Bhāskara I (the commentary of Paramesvara on this line is vague and misleading). Sūryadeva in this connection says :

Here by the word *gunakāra* is meant the multiplier and multiplicand, i.e., the *phala* and *icchā* quantities that are multiplied together. By *Bhāgahāra* is meant the *pramāṇa* quantity. The denominators of the *phala* and *icchā* are taken to the *pramāṇa*. The denominator of the *pramāṇa* is taken with the *phala* and *icchā*. Then multiplying these, i.e., (the numerators of) the *phala* and *icchā* and this denominator, and dividing by (the product of) the numbers standing with the *pramāṇa* the result is the quotient of the fractions.

Brahmagupta gives the method of division as follows :

The denominator and numerator of the divisor having been interchanged, the denominator of the dividend is multiplied by the (new) numerator. Thus division of proper fractions is performed.¹

Square and Square-Root of Fractions

Brahmagupta says as follows in this connection:—

The square of the numerator of a proper fraction divided by the square of the denominator gives the square.²

This rule of Brahmagupta has been followed by other authors also. The rule regarding the square-root as given by Brahmagupta is as follows :

The square-root of the numerator of a proper fraction divided by the square-root of the denominator gives the square-root.³

The Rule of Three :

The Indian term in Sanskrit for the Rule of Three is *Trairāsika* (literally, "three terms"). The term occurs in the *Bakhshali Manuscript* also, and also in the *Āryabhaṭṭya*, indicating the

1. अरित्यं भागहारच्छेदांशौ द्वे संगुणच्छेदः ।
अंशोऽशमणो भाज्यस्य भागहारः सर्वांशतयोः ॥ —BrSpSi. XII. 4

2. संवर्धितं शक्यं रश्चेद्वृत्तिविभाजितो भवति वर्गः । —BrSpSi. XII. 5 (1)

3. संवर्धितं शक्यं रश्चेद्वृत्तिविभाजितो भवति मूलम् । —BrSpSi. XII. 5 (2)

antiquity of the term. Bhāskara in his commentary of the *Āryabhaṭīya* gives a justification of the use of this term for the Rule of Three thus :

Here three quantities are needed (in the statement and calculation) so the method is called *trairāśika* (meaning thereby the "rule of three terms").

The problem of the Rule of Three has the form :

If p (*pramāṇa*) yields f (*phala*), what will i (*icchā*) yield ?

Āryabhaṭa II (the author of the *Mahāsiddhānta*, 950 A.D.) uses the terms *māna*, *vinimaya* and *icchā*, instead of *pramāṇa*, *phala* and *icchā* respectively. It has also been pointed out by several authors that the first and third terms are similar, i.e., of the same denomination.

We shall give here the Rule of Three as given by Āryabhaṭa I and Brahmagupta :

In the Rule of Three, the *phala* ("fruit"), being multiplied by the *icchā* ("requisition") is divided by the *pramāṇa* ("argument"). The quotient is the fruit corresponding to the *icchā*. The denominators of one being multiplied with the other give the multiplier (i.e. numerator) and the divisor (i.e. denominator).¹

In the Rule of Three *pramāṇa* ("argument"), *phala* ("fruit") and *icchā* ("requisition") are the (given) terms; the first and the last terms must be similar. The *icchā* multiplied by the *phala* and divided by the *pramāṇa* gives the fruit (of the demand).²

Śrīdhara also gives the Rule of Three almost in the same words. Bhāskara II, Nārāyaṇa and others follow Brahmagupta and Śrīdhara in the *Trairāśika* operation. Śrīdhara in his *Pāṅganita* says :

1. त्रैराशिकफलराशि तमयेच्छाराशिनाहतं कृत्वा ।
लब्धं प्रमाणभजितं तस्मादिच्छाफलमिदं स्यात् ॥
छेदाः परस्परं हता भवन्ति गुणकार भागहराणां ।
छेदगुणं सच्छेदं परस्परं तत्सर्वार्थत्वम् ॥

—Arya: II 26-27.

2. त्रैराशिके प्रमाणं फलमिच्छावन्तयोः सदृशराशी ।
इच्छाफलेन गुणितं प्रमाणभक्ता फलं भवति ॥

—BrSpSi XII. 10

In (solving problems on) the Rule of Three, the argument (*pramāṇa*) and the requisition (*icchā*), which are of the same denomination, should be set down in the first and last places; the fruit (*phala*), which is of a different denomination, should be set down in the middle. (this having been done) that (middle quantity multiplied by the last quantity should be divided by the first quantity.¹

We shall illustrate the Rule of Three by an example from the *Pāṇjanita* (Example 25) :

Example, If 1 *pala* and 1 *karṣa* of sandalwood are obtained for ten and a half *panas*, then for how much will nine *palas* and one *karṣa* (of sandalwood) be obtained ?²

Here in this Example.

argument = 1 *pala* and 1 *karṣa* = $1\frac{1}{2}$ or $5/4$ *palas*; fruit = $10\frac{1}{2}$ or $21/2$ *panas*;

and requisition = 9 *palas* and 1 *karṣa* = $9\frac{1}{2}$ or $37/4$ *palas*.

According to the Rule we shall write them as :

$$\begin{array}{|c|c|c|} \hline 1 & 10 & 9 \\ \hline 1 & 1 & 1 \\ \hline 4 & 2 & 4 \\ \hline \end{array}$$

Converting these into proper fractions we have

$$\begin{array}{|c|c|c|} \hline 5 & 21 & 37 \\ \hline 4 & 2 & 4 \\ \hline \end{array}$$

Then applying the rule, (i.e. multiplying the second and the last and dividing by the first), we have

$$\begin{array}{|c|c|} \hline 21 & 5 \\ \hline 2 & 4 \\ \hline 37 & \\ \hline 4 & \\ \hline \end{array}$$

$$\frac{21}{2} \times \frac{37}{4} = \frac{5}{4}$$

Or transferring denominators $\begin{array}{|c|c|} \hline 21 & 5 \\ \hline 4 & 2 \\ \hline 37 & 4 \\ \hline \end{array} = \frac{21.4.37}{5.2.4} \text{ pala}$

1. भाष्यन्तरोत्तराशावभिन्नजाती प्रमाणमिच्छा च ।

— *Pāṇjanita* 43.

— *Pāṇjanita*. Ex. 25.

=4 purāṇa, 13 paṇas, 2 kākiṇis and 16 varātakas. (One purāṇa is equivalent to 16 paṇas; one paṇa is equivalent to 4 kākiṇis, and One kākiṇi is equivalent to 20 varātakas or cowries.

Inverse Rule of Three

This is known as *vyasta-trairāśika* (literally meaning "inverse rule of three terms"). After having described the rule of three, Brahmagupta proceeds to give an account of this inverse rule of three :

Divide the *phala* with *icchā* and multiply by *pramāṇa*; this gives the *vyasta-trairāśika* inverse rule of three¹.

Here *pramāṇa* is the argument also known as the first term and, and *phala* is the fruit also known as the middle term and *icchā* is known as requisition or the last term. As Bhāskara II clearly states, this rule is applied where with the increase of the *icchā*, the *phala* decreases or with its decrease the *phala* increases (*Līlavatī*).

Rule of Compound Proportion

Brahmagupta and other writers call the rule of compound proportions as *pañca-rāśika*, *sapta-rāśika* etc., meaning the rule of five terms, rule of seven terms etc. depending on the number of terms involved the problems. These are sometimes grouped under the general application of the "Rule of Odd Terms". Āryabhaṭa I (499 A.D.) though actually gives the rule of three appears to have been quite familiar with the rule of compound proportion also. In fact the difference between the rule of three and compound proportion is more or less artificial. This view was expressed by Bhāskara I (525 A.D.) in his commentary on the *Āryabhaṭa* :

Here Ācārya Āryabhaṭa has described the Rule of Three only. How the well-known Rules of Five etc. are to be obtained ? I say thus : The Ācārya has described only the fundamentals of *anupāta* (proportion). All others such as the Rule of Five etc. follow from that fundamental rule of proportion. How ? The Rule of Five etc. consist of combinations of the Rule of Three.In the Rule of Five, there are two Rules of

1. व्यस्त त्रैराशिक फलसिद्धिा भवतः प्रमाणं फलकतः ।
त्रैराशिकादियु फलं विभजेन्नेकादशान्तेषु ॥

Three, in the Rule of Seven three Rules of Three, and so on. This I shall point out in the examples.

Brahmagupta gives the following rule relating to the solution of problems in compound proportion :

In the case of odd terms beginning with three terms up to eleven, the result is obtained by transposing the fruits of both sides, from one side to the other, and then dividing the product of the larger set of terms by the product of the smaller set. In all the fractions, the transposition of denominators, in like manner, takes place on both sides.¹

This may be illustrated by taking an example from the commentary of Prthudaka Svāmi on the *Brāhmasphuṭasiddhānta* :

Example — If there is an increase of 10 in 3 months on 100 (*niṣkas*), what would be the increase on 60 (*niṣkas*) in 5 months.

Here the *Pramāṇa pakṣa* (the first set of terms) is 100 *niṣkas*, 3 months, 10 *niṣkas* (*phala*)

The second set or the *icchā pakṣa* is 60 *niṣkas*, 5 months, *x niṣkas*

The terms are written in compartments as below :

100	60
3	5
10	0

In the above 10 (written lowest) is the *fruit* of the first side (*pramāṇa pakṣa*), and there is no *fruit* on the second side or the *icchā pakṣa*. Interchanging the *fruits* we get

100	60
3	5
0	10

The larger set of terms is on the second side (*icchā pakṣa*). The product of the numbers is 3,000. The product of the

1. व्यस्त त्रैशिक, फलमिच्छा भक्तः प्रमाणफलवातः ।

त्रैशिकादिषु फलं विपर्ययेकादशान्तेषु ॥

फलसंक्रमणमुपयतो बहुशशि वचोऽल्पवचहतो ज्ञेयम् ।

सकलेष्वेवं मिनेषुमदितस्येदसंक्रमणम् ॥

—BrSpSi: XII. 11-12.

number on the side of the smaller set of terms is 300. Therefore the required result is $\frac{3000}{300} = 10$.

Rule of Three as a Particular Case

According to, Brahmagupta, the above method of "compound proportion" may be applied to the Rule of Three. Taking the example solved under the Rule of Three:

If one *pala* and one *karṣa* of sandal wood are obtained for ten and a half *panas*, for how much will be obtained nine *palas* and one *karṣa*?

(4 *karṣas* = 1 *pala*).

We shall represent them according to the Rule of Compound Proportion as

Pramāṇa pakṣa : 1 *pala*, 1 *karṣa*, 10½ *pana*
 or $\frac{5}{4}$ *pala*, $\frac{21}{4}$ *pana*,
Icchā pakṣa : 9 *pala*, 1 *karṣa*, x *pana*
 or 37¼ *pala*, x *pana*

This we shall represent as

5	37
4	4
21	0
2	

Transposing the fruits, we have

5	37
4	4
0	21
2	

Transposing denominators

5	37
4	4
0	21
2	

The product of numbers on the side of the larger set is divided by the product of the numbers on the side of the smaller set, 0 in this case is not a number. It is the symbol for the unknown or absence. Hence the result is:

$$\frac{37.4.21}{5.4.2} \text{ panas}$$

The above method of working Rule of Three is found among Arabs, although it does not seem to have been used in India after Brahmagupta.

Problem Containing Quadratic Equation

Perhaps Āryabhaṭa I is the first man in the history of mathematics to give a solution of a quadratic equation (499 A.D.). In his *Āryabhaṭīya*, he gives a rule for the solution of the following problem (I am reproducing it as described by Datta and Singh):

The principal sum p ($=100$) is lent for one month (interest unknown $=x$). This unknown interest is then lent out for t ($=\text{six}$) months. After this period, the original interest (x) plus the interest on this interest amounts to A ($=16$). The rate-interest (x) on the principal (p) is required.

This problem requires the solution of the quadratic equation:—

$$tx^2 + px - Ap = 0$$

which gives $x = \frac{-p/2 \pm \sqrt{(p/2)^2 + Apt}}{t}$

The negative value of the radical does not give a solution of the problem; so that the result is

$$x = \frac{\sqrt{Apt + (p/2)^2} - p/2}{t}$$

This solution is stated by Āryabhaṭa I in the following words:

Multiply the sum of the interest on the principal and the interest (A) by the time (t) and by the principal (p). Add to this result the square of half the principal $(p/2)^2$. Take square-root this. Subtract half the principal ($p/2$) and divide the remainder by the time (t). The result will be the (unknown) interest (x) on the principal.¹

Here the Sanskrit terms are *mūla* for principal and *phala* for interest.

1. मूलफलं सफलं कालमूलगुणमर्धमूलकृत्तियुक्तं ।

मूलं मूलार्धेन कालद्वयं त्वास्मैमूलफलम् ॥

Brahmagupta (628 A.D.) gives a more general rule : He enunciates his problem thus :

The principal (p) is lent out for t_1 months and the unknown interest on this ($=x$) is lent out for t_2 months at the same rate and becomes A . To find x .

This evidently gives the quadratic :

$$x^2 + \frac{pt_1}{t_2} x - \frac{Apt_1}{t_2} = 0$$

whose solution is

$$x = \pm \sqrt{\frac{Apt_1}{t_2} + \left(\frac{pt_1}{2t_2}\right)^2} - \frac{pt_1}{2t_2}$$

The negative value of the radical does not give a solution of the problem, so it is discarded.

Brahmagupta states the formula thus :

Multiply the principal (p) by its time (t_1) and divide by the other time (t_2) (placing the result) at two places. Multiply the first of these by the mixture (A). Add to this the square of half the other. Take the square-root of this (sum). From the result subtract half the other. This will be the interest (x) on the principal.¹

A Problem on Interest

Brahmagupta gives a solution of a problem on interest :

In what time will a given sum s , the interest on which for t months is r , become k times itself ?

The rule for the solution of this problem as given by Brahmagupta is :

The given sum multiplied by its time and divided by the interest (*phala*), being multiplied by the factor (*guna*) less one, is the time (*required*).²

Miscellaneous Problems

Brahmagupta in his *Ganitadhyaya* of the *Brahmasphuṭa-siddhanta* gives numerous solutions in relation to miscellaneous problems. Here I shall be quoting a few of the problems which

1. कालप्रमाणघातः परकालद्वयो दिवाऽऽवमिश्रवधात् ।

अन्यार्धकृतियुतात् पदमन्यार्धेन प्रमाणफलम् ॥

2. कालगुणितं प्रमाणं फलभक्तं व्येकगुणद्वतं कालः ।

स्वफलयुतरूपभक्तं मूलफलैक्यं भवति मूलम् ॥

—BrSpSi. XII. 15.

—BrSpSi. XII. 14.

have been quoted by his commentator Pṛthūdaka Svāmī in connection with one of his karaṇa-sūtra.¹

1. A horse was purchased by (nine) dealers in partnership, whose contributions were one, etc. up to nine; and was sold by them for five less than five hundred. Tell me what was each man's share of the sale proceed²
2. Four colleges (mathas), containing an equal number of pupils, were invited to partake of a sacrificial feast. A fifth, a half, a third and a quarter (of the total number of pupils in the college) came from the respective colleges to the feast; and added to one, two, three and four, they were found to amount to eighty-seven; or, with those deducted, they were sixty seven. Find the actual number of the pupils that came from each college.³
3. Three (unequal) jars of liquid butter, of water and of honey, contained thirty-two, sixty and twenty-four *Pala* respectively; the whole was mixed together and the jars filled again. Tell me the quantity of butter, of water and of honey in each jar⁴.

1. प्रक्षेपयोगहृतया लब्ध्वा प्रक्षेपका गुण्या लाभः ।

ऊनाधिकोत्तरास्तद्युतो नया स्वफलमूनयुत ॥

BrSpSi. XII. 16.

2. एकार्थैर्नव पर्यन्तैर्विंशैर्मूलराशिभिः ।

क्रीतो ब्योऽसौ विक्रीतः पञ्चोनैः पञ्चोनैः पञ्चभिः शतैः ।

किमैकैकस्य तत्रासीद् ब्रूहि त्वं मिश्रकान् मम ॥

3. मठस्थानानि चत्वारि छात्राणां समसंख्यया ।

भोक्तुं संमन्त्रितान्यासन् दीक्षायां किल बज्जना ॥

पञ्चार्धचिचतुर्थारास्तेभ्यो भोक्तुं समागताः ।

एकदिचिचतुर्थे क्ता दद्यादितिः सप्तसका ॥

एवोत्तरैरथवा द्वीना सप्तषष्टिश्चतैः शकाः ।

मठेभ्यश्छान्संख्यां ज्ञेयं ब्रूहि ये क्षमता कतः

4. धृतोदकमधूनां ये ज्ञयः कलसकाः पलैः ।

रदषष्टिभिः पूर्या एकीभूतास्ततः पुनः ॥

मिश्रेण पूरिता यावत् तावत् संख्यां न वेदन्यहम् ।

धृतोदकमधूनां तमेकैकत्र गतां वद ॥

CHAPTER IX

Brahmagupta as an Algebraist

Ancient Indian name for algebra is *Bijaganita* where *bija* means *element* or *analysis* and *ganita* stands for the *science of calculation*. As early as 860 A.D., Pṛthūdaka Svāmi used this epithet for algebra in his commentary. Brahmagupta calls algebra as *Kuṭṭakaganita* or merely *kuṭṭaka*, a term which was later on used for "*pulveriser*" which deals with that special section of algebra which is connected with indeterminate equations of the first degree. Algebra is often also known as *avyakta-ganita* or the calculations with *unknowns*, in contrast to arithmetic which was known as *vyakta-ganita* or the calculations with *knowns*.

Algebra goes to Europe from India

In the history of mathematical sciences, as Colebrooke rightly remarks, it has long been a question to whom the invention of algebraic analysis is due. There is no doubt that Europe got algebra from Arabs mediately or immediately. But the Arabs themselves scarcely pretend to the discovery of algebra. Colebrooke says that they were not in general inventors but scholars during the short period of their successful culture of the sciences; and the germ at least of the algebraic analysis is to be found among the Greeks in an age not precisely determined, but more than probably anterior to the earliest dawn of civilisation among the Arabs; and this science in a more advanced state subsisted among the Hindus prior to the earliest disclosure of it by the Arabians to modern Europe. (Colebrooke: *Dissertation on the Algebra of the Hindus*)¹.

Colebrooke based his observations on the texts he could procure for his studies. These were: Bhāskara II's *Bijaganita* or *Vijaganita* (1150 A.D.) and *Līlāvati* (1150 A.D.), the *Gaṇitāḍhyāya* and *Kuṭṭakāḍhyāya* of Brahmagupta in his famous treatise the *Brahma Siddhānta* or rather the *Brahmasphuṭasiddhānta* (628

1. Colebrooke, H. T., *Miscellaneous Essays*, Vol. II, 1872, p. 418.

A.D.). There can be no doubt regarding the age of these two authors. Bhāskara II completed his great work on the *Siddhanta-siromani* in 1072 Śaka, and *Karaṇa-kutūhala* a practical astronomical treatise in 1105 Śaka; these dates are based on the passages given by Bhāskara himself in his works. The *Bija-ganita* and the *Lilāvati* form parts of the great treatise, the *Siddhanta-siromani*. The genuineness of the text is established, as Colebrooke says, with no less certainty by numerous commentators in Sanskrit, besides a Persian version of it. Those commentaries comprise a perpetual gloss, in which every passage of the original is noticed and interpreted : and every word of it is repeated and explained. From comparison and collation of various texts, it appears then that the work of Bhāskara, exhibiting the same uniform text which the modern transcripts of it do, was in the hands of both Muhammedans and Hindus, between two or three centuries ago : and numerous copies of it having been diffused throughout India, at an earlier period, as of a performance held in high estimation, It was the subject of study and habitual reference in countries and places so remote from each other as the north and west of India and the Southern Peninsula.

This though not marking any extraordinary antiquity, nor approaching to that of the author himself, was a material point to be determined : as there will be in the sequel so says Colebrooke, occasion to show, that modes of analysis, and in particular, general methods for the solution of indeterminate problems both of the first and second degrees, are taught in the *Bija-ganita*, and those for the first degrees repeated in the *Lilāvati*, which were unknown to the mathematicians of the West, until invented anew in the last two centuries by algebraists of France and England.¹ Bhāskara who himself flourished more than six hundred and fifty years ago, was in this respect a compiler and took those methods from Indian authors as much more ancient than himself.

Regarding the age of the precursors of Bhāskara II, Colebrooke says : The age of his precursors cannot be determined with equal precision. He then proceeds to examine the evidence as follows :

¹ Colebrooke, H. T., *Miscellaneous Essays*, p. 421.

Towards the close of his treatise on Algebra, Bhāskara II informs us, that it is compiled and abridged from the more diffuse works on the same subject, bearing the names *Brāhme* (meaning no doubt Brahmagupta), Śrīdhara and Padmanābha; and in the body of his treatise, he has cited a passage of Śrīdhara's algebra and another of Padmanābha. He repeatedly adverts to preceding writers and refers to them in general terms, where his commentators understand him to allude to Āryabhata, to Brahmagupta to the latter's scholiast Caturveda *Prthūdaka Svāmī* and to the other writers above mentioned.

Most, if not all, of the treatises, to which he thus alludes, must have been extant, and in the hands of his commentators, when they wrote; as appears from their quotations of them; more especially those of Brahmagupta and Āryabhata, who are cited, and particularly the first mentioned, in several instances. A long and diligent research in various parts of India, has, however, failed of recovering any part of the *Padmanābha Bija* (or the algebra of Padmanābha) and of the algebraic and other works of Āryabhata.

But the translator has been more fortunate in regard to the works of Śrīdhara and Brahmagupta, having in his collection Śrīdhara's compendium of arithmetic, and a copy incomplete however, of the text and scholia of Brahmagupta's *Brahmasiddhānta* comprising among other no less interesting matter, a chapter treating of arithmetic and mensuration; and another, the subject of which is algebra: both of them fortunately complete. The commentary is a perpetual one; successively quoting in length each verse of the text; proceeding to the interpretation of it, word by word; and subjoining elucidations and remarks; and its colophon, at the close of each chapter, gives the title of the work and the name of the author. Now the name which is there given, Caturveda *Prthūdaka Svāmī*, is that of a celebrated scholiast of Brahmagupta, frequently cited as such by the commentaries of

Bhāskara and by other astronomical writers; and the title of the work, *Brahmasiddhānta* or sometimes *Brahmasphuṭasiddhānta*, corresponds, in the shorter form, to the known title of Brahmagupta's treatise in the usual references to it by Bhāskara's commentators, and answers, in the longer form, to the designation of it, as indicated in an introductory couplet which is quoted from Brahmagupta by Lakṣmidāsa, a scholiast of Bhāskara II. Remarking this coincidence, the translator proceeded to collate, with the text and commentary, numerous quotations from both, which he found in Bhāskara's writings or in those of his expositors. The result confirmed the indication and established the identity of both text and scholia as Brahmagupta's treatise, and the gloss of Pṛthūdaka. The authenticity of the *Brahmasiddhānta* is further confirmed by numerous quotations in the commentary of Bhaṭṭotpala on the *Samhitā* of Varāhamihira : as the quotations from the *Brahmasiddhānta*, in that commentary, (which is the work of an author who flourished eight hundred and fifty years ago) are verified in the copy under consideration. A few instances of both will suffice, and cannot fail to produce conviction.

It is confidently concluded, that the chapters on arithmetic and algebra, fortunately entire in a copy in many parts imperfect, of Brahmagupta's celebrated work as here described, are genuine and authentic. It remains to investigate the age of the author.

Mr. Davis, who first opined to the public a correct view of the astronomical computations of the Hindus, is of opinion, that Brahmagupta lived in the seventh century of the Christian era. Dr. William Hunter, who resided for some time with a British Embassy at Ujjayini, and made diligent researches into the remains of Indian science at that ancient seat of Hindu astronomical knowledge, was there furnished, by the learned astronomers whom he consulted, with the ages of the principal ancient authorities. They assigned to Brahmagupta the date of 550 Saka; which answers to A.D.

628. The grounds on which they proceeded are unfortunately not specified: but as they gave Bhāskara's age correctly, as well as several other dates right, which admit of being verified; it is presumed that they had grounds, though unexplained, for the information which they communicated.

Mr. Bentley, who is little disposed to favour the antiquity of an Indian astronomer, has given his reasons for considering the astronomical system which Brahmagupta teaches, to be between twelve and thirteen hundred years old (1263 years in A.D. 1799). Now as the system taught by this author is professedly one corrected and adapted by him to conform with the observed positions of the celestial objects when he wrote, the age, when their positions would be conformable with the results of computations made as by him directed, is precisely the age of the author himself: and so far as Mr. Bentley's calculations may be considered to approximate the truth, the date of Brahmagupta's performance is determined with like approach to exactness, within a certain latitude however of uncertainty for allowance to be made on account of the inaccuracy of Hindu observations.

The translator has assigned on former occasions the grounds upon which he sees reason to place the author's age, soon after the period when the vernal equinox coincided with the beginning of the lunar mansion and zodiacal asterism *Āśvini*, where the Hindu ecliptic now commences. He is supported in it by the sentiments of Bhāskara and other Indian astronomers, who infer from Brahmagupta's doctrine concerning the solstitial points, of which he does not admit a periodical motion, that he lived when the equinoxes did not, sensibly to him, deviate from the beginning of *Āśvini* and middle of *citra* on the Hindu sphere. On these grounds it is maintained, that Brahmagupta is rightly placed in the sixth or beginning of the seventh century of the Christian era, as the subjoined calculations will more particularly show. The age when Brahmagupta

flourished, seems then, from the concurrence of all these arguments, to be satisfactorily settled as antecedent to the earliest dawn of the culture of sciences among the Arabs; and *consequently establishes* the fact, that *the Hindus were in possession of algebra before it was known to the Arabians.*

Brahmagupta's treatise, however, is not the earliest work known to have been written on the same subject by an Indian author. The most eminent scholiast of Bhāskara II (Gaṇeśa) quotes a passage of Āryabhaṭa specifying algebra under the designation of *Bija*, and making separate mention of *Kuṭṭaka*, which more particularly intends a problem subservient to the general method of resolution of indeterminate problems of the first degree : he is understood by another of Bhāskara's commentators to be at the head of the elder writers, to whom the text then under consideration adverts, as having designated by the name of *Madhyamāharaṇa* the resolution of affected quadratic equations by means of the completion of the square. It is to be presumed, therefore, that the treatise of Āryabhaṭa then extant, did extend to quadratic equations in the determinate analysis, and to indeterminate problems of the first degree; if not to those of the second likewise, as most probably it did.

This ancient astronomer and algebraist, so says Colebrooke, was anterior to both Varāhamihira and Brahmagupta, being repeatedly named by the latter; and the determination of the age when he flourished is particularly interesting as his astronomical system, though on some points agreeing, essentially disagreed on others, with that which the Hindu astronomers still maintain.

He, as Colebrooke says, is considered by the commentators of the *Śūryasiddhānta* and *Śiromaṇi*, as the earliest of uninspired and mere human writers on the science of astronomy, as having introduced requisite corrections into the system of Parāśara, from whom he took the numbers for the planetary mean motions; as

having been followed in the tract of emendation, after a sufficient interval to make further correction requisite, by Durgāsinha and Mihira; who were again succeeded after a further interval by Brahmagupta, son of Jīṇu.

In short, says Colebrooke, Āryabhaṭa was founder of one of the sets of Indian astronomers, as Puliśa, an author likewise anterior to both Varāhamihira and Brahmagupta, was of another : which were distinguished by names derived from the discriminative tenets respecting the commencement of planetary motions at sunrise according to the first, but at midnight according to the latter, on the meridian of Lāṅkā, at the beginning of the great astronomical cycle. A third sect began the astronomical day, as well as the great period, at noon.

Āryabhaṭa's name accompanied the intimation which the Arab astronomers (under the Abbasside Khalifs, as it would appear,) received, that three distinct astronomical systems were current among the Hindus of those days : and it is but slightly corrupted, certainly not at all disguised, in the Arabic representation of it *Arjabahar*, or rather *Arjabhar*, (corrupted form of Āryabhaṭa). The two other systems were, first, Brahmagupta's *Siddhānta* which was the one they became best acquainted with, and to which they apply the denomination of the *sind-hind*; and second, that of *Arca*, the Sun, which they write *Arcand* a corruption still prevalent in the vulgar Hindi.

Āryabhaṭa appears to have had more correct notions of the true explanation of celestial phenomena than Brahmagupta himself, so says Colebrooke; who in a few instances, correcting errors of his predecessor, but oftener deviating from that predecessor's juster views, has been followed by the herd of modern Hindu astronomers, in a system not improved, but deteriorated, since the time of the more ancient author.

Considering the proficiency of Āryabhaṭa in astronomical science, and adverting to the fact of his having

written algebra, as well as to the circumstance of his being named by numerous writers as the founder of a sect, or author of a system in astronomy, and being quoted at the head of algebraists, when the commentators of extant treatises have occasion to mention early and original writers on this branch of science, it is not necessary to seek further for a mathematician qualified to have been the great improver of the analytic art, and likely to have been the person by whom it was carried to the pitch to which it is found to have attained among the Hindus, and at which it is observed to be nearly stationary through the long lapse of ages which have since passed : the later additions being few and unessential in the writings of Brahmagupta, of Bhāskara and of Jñānarāja, though they lived at intervals of centuries from each other.

Āryabhaṭa, Colebrooke rightly says, then being the earliest author known to have treated of Algebra among the Hindus, and being likely to be, if not the inventor, the improver of that analysis, by whom too it was pushed nearly to the whole degree of excellence which it is found to have attained among them; it becomes in an especial manner interesting to investigate any discoverable trace in the absence of better and more direct evidence, which may tend to fix the date of his labours; or to indicate the time which elapsed between him and Brahmagupta, whose age is more accurately determined.

Taking Āryabhaṭa, for reasons given, to have preceded Brahmagupta and Varāhamihira by several centuries; and Brahmagupta to have flourished more than twelve hundred years ago, and Varāhamihira, concerning whose works and age, Colebrooke has given a few notes, and has placed him at the beginning of the sixth century after Christ, it appears probable that this earliest of known Hindu algebraists wrote as far back as the fifth century of the Christian era; and perhaps in an earlier age. Hence it is concluded that he is nearly as ancient as the Grecian algebraist Diophantus, sup-

posed on the authority of Abulfaraj, to have flourished in the time of the Emperor Julian or about A. D. 360.

Colebrooke further says: Admitting the Hindu and Alexandrian authors to be nearly equally ancient, it must be conceded in favour of the Indian algebraist, that he was more advanced in the science; since he appears to have been in possession of the resolution of equations involving several unknowns, which it is not clear, nor fairly presumable, that Diophantus, knew; and a general method of indeterminate problems of at least the first degree, to a knowledge of which the Grecian algebraist had certainly not attained; though he displays infinite sagacity and ingenuity in particular solutions; and though a certain routine is indiscernible in them.

Colebrooke appears to be of the view that Greeks were the first to discover the solution of equations involving one unknown; and this knowledge was passed to ancient Indians by their Greek instructors in improved astronomy. But "by the ingenuity of the Hindu-scholars, the hint was rendered fruitful and the algebraic method was soon ripened from that slender beginning to the advanced state of a well arranged science, as it was taught by Āryabhata, and as it is found in treatises compiled by Brahmagupta and Bhāskara."

We do not agree with this analysis in entirety. Indian algebra is entirely of Indian roots. It had its beginning in the times of Samhitās and Brāhmanas. Some of the equations and problems were solved by geometric methods. It must have had its origin in the Śulba period if not before. Āryabhata undoubtedly was the discoverer of many algebraic solutions of equations of the first and higher order with one and more unknowns. It is rather too much to trace the influence of Diophantus on Indian algebra which developed in this country independently. Brahmagupta is one of the most brilliant algebraists we ever had in the entire history of mathematics.

Technical Terms

Coefficient—

In the ancient Indian algebra, there is no systematic term for the coefficient. Usually, the power of the unknown is mentioned when the reference is to the coefficient of that power. At one place, for example, we find Pṛthūdaka Svāmī (the commentator of Brahmagupta's *Brahmasphuṭasiddhānta*) writing "the number (*aṅka*) which is the coefficient of the square of the unknown is called the 'square' and the number which forms the coefficient of the (simple) unknown is called the 'unknown quantity' (*avyakta-māna*)."¹ However, at many places, we find the use of a technical term also. Brahmagupta once calls the coefficient *saṁkhyā*² (number) and on several other occasions *guṇaka*³ or *guṇakāra*⁴ (multiplier). Pṛthūdaka Svāmī (860 A.D.) calls it *aṅka* (number) or *prakṛti* (multiplier). These terms may also be seen in the works of Śrīpati⁵ (1039) and Bhāskara II⁷ (1150 A.D.). The former also used the word *rūpa* for the same purpose.⁸

Unknown Quantity

The unknown quantity has been termed as *yāvat-tāvat* (meaning so-much-as or as-many-as) in literature as early as 300 B. C. (vide the *Sthānāṅga-sūtra*⁹). In the *Bakhasālī Manuscript*, it has been termed as *yadycchā*, *vāñchā* or *kāmikā* (or any desired quantity)¹⁰. Āryabhaṭa I in one of his verses calls the unknown as *gulika*¹¹ (literally meaning a shot) From the early seventh century A.D., the word *avyakta* was used for unknown quantities. Brahmagupta uses this term in his *Brahmasphuṭasiddhānta*¹²

Power

Since long, the word *varga* has been used for the second power; the word also stands for *square* (*Uttarādhyaṇa Sūtra*¹, B. C. c. 300). The third power is similarly known as *ghana*, the fourth power as *varga-varga* (square-square), the sixth power as *ghana-varga* (cube-square) and the twelfth power as *ghana-varga-varga* (cube-square-square). In later days, the fifth power was called *vargaghana ghāta* (here the word *ghāta* means product; the term means product of cube and square). The former system was multiplicative, rather than additive; whereas the latter was on the additive system. The seventh power on the additive system was known as *varga-varga-ghana-ghāta* (product of square-square and cube). Brahmagupta, however, uses a more scientific system for expressing the powers more than four. He calls the fifth power as *Pañca gata* (literally meaning, raised to the fifth), the sixth power as *ṣaḍ-gat* (raised to the sixth) and so on, thus adding the suffix *gata* to the name of the number indicating that power.² Bhāskara II has followed the system of Brahmagupta almost consistently for powers one and upwards.

Equation

Perhaps Brahmagupta has for the first time used the term *samakarana* or *samakarāṇa* (literally meaning making equal) or simply *sama* (equal or equation)³. Pṛthudaka Svāmī (860) employs the term *sāmya* (equality or equation) for equation⁴. The equation is said to possess two *Pakṣas*⁵ (sides) *Itara-Pakṣa* and *apara-pakṣa*.

Absolute Term

Brahmagupta uses the term *rūpa* (literally meaning appearance) for an absolute term. It represents the visible or known

5. *Bījagaṇita*.

portion of the equation whilst its other part is practically invisible or unknown¹.

Unknowns and Symbolism

Āryabhaṭa I (499 A. D.) probably used coloured *gulikas* or shots for representing different unknowns. Brahmagupta mentions *varṇa* as the symbols for unknown. He has, however, not indicated how these *varṇas* or colours were used as symbols for unknowns. Perhaps we might conclude from this that the method of using colours as symbols for unknown quantities was very common and familiar to the algebraists. Datta and Singh say that the Sanskrit word *varṇa* denotes colour as well as a letter of alphabet, and therefore, letters of alphabet came into use for unknown quantities: *kālaka* (black), *nilaka* (blue), *pītaka* (yellow), *lohita* (red), *haritaka* (green), *śvetaka* (white), *citraka* (variegated), *kapilaka* (tawny), *pingalaka* (reddish-brown), *dhūmraka* (smoke-coloured), *pāṭalaka* (pink), *śaralaka* (spotted), *syāmalaka* (blackish), *mecaka* (dark blue) etc.².

It should be further noted that the first unknown quantity *yāvat-tāvat* is not a *varṇa* or colour. It thus clearly indicates that the use of colours as symbols came at a later stage, whilst the word *yāvat-tāvat* was in currency from much earlier times. Some authorities think that the term *yāvat-tāvat* is a corrupted form of *yāvakaśtāvat* (where *yāvaka* means red). Pṛthūdaka Svāmī has sometimes used the term *yāvaka* for an unknown quantity³.

Laws of Signs

Brahmagupta has in his Chapter XVIII devoted a special section entitled "*Dhanarṇa Śūnyānam Samkalanam*" or calculations dealing with quantities bearing positive and negative signs and zero,

1. अव्यक्तान्तरं भक्तं व्यस्तं रूपान्तरं समेऽव्यक्तः । —BrSpSi XVIII. 43

3. BrSpSi XII. 15. (Com.) ; XII 18.

Regarding *addition*, Brahmagupta says :

The sum of two positive numbers is positive, of two negative numbers is negative; of a positive and negative number is the difference¹.

Regarding *subtraction*, Brahmagupta further says :

From the greater should be subtracted the smaller; (the final result is) positive, if positive from positive, and negative, if negative, from negative. If, however, the greater is subtracted from the less, that difference is reversed (in sign), negative becomes positive and positive becomes negative. When positive is to be subtracted from negative or negative from positive, then they must be added together².

Mahāvira (850 A. D.), Bhāskara II (1150 A.D.) and Nārāyaṇa (1350 A. D.) have also given similar rules regarding addition (*Saṅkalanam*) and the subtraction (*vyavakalanam*).

Again, the rule given by Brahmagupta regarding *Multiplication* is as follows :

The product of a positive and a negative (number) is negative; of two negatives is positive; positive multiplied by positive is positive³.

His rule regarding *division* is as follows ;

Positive divided by positive or negative divided by negative becomes positive. But positive divided by negative and negative divided by positive remains negative⁴.

Similar rules for multiplication and division were provided by later authorities as Mahāvira and Bhāskara II.

Brahmagupta lays down the rules regarding *evolution* and *involution* as follows :

The square of a positive or a negative number is positive
.....The (sign of the) root is the same, as was that from which the square was derived¹.

As regards the latter portion of this rule, Pṛthūdaka Svāmī has the following comment to make : "The square-root should be taken either negative or positive, as will be most suitable for subsequent operations to be carried on."

It will be interesting to observe the following observation of Mahāvīra (850 A. D.) regarding square-root of a negative quantity "Since a negative number by its own nature is not a square, it has no square-root."² So says Śrīpati : "A negative number by itself is non-square, so its square-root is unreal; so the rule (for the square-root) should be applied in the case of a positive number."³

Algebraic Operations

Brahmagupta and other algebraists recognise six operations as fundamental in algebra : addition, subtraction, multiplication, division, squaring and the extraction of the square-root.

Regarding *addition* and *subtraction* Brahmagupta says :

Of the unknowns, their squares, cubes, fourth powers, fifth powers, sixth powers, etc., addition and subtraction are (performed) of the like; of the unlike (they mean simply their) statement severally.⁴

In place of "of the like", Bhāskara II uses the term "of those of the same species (*jāti*) amongst unknowns" :

Addition and subtraction are performed of those of the same species (*jāti*) amongst unknowns; of different species they mean their separate statement.⁵

1. खोदधृत मृणं धनं वा तच्छेदं खमृणधनविभक्तं वा ।

ऋणधनयोर्वर्गः स्वं स्वं स्वस्य पदं कृतिर्यत् तत् ॥

—BrSpSi, XVIII. 35

2. GSS, I, 52.

3. Śiśe, XIV, 5.

4. अव्यक्तवर्गं धनवर्गं वर्गं पंचगतं षड्गतादीनाम् ।

तुल्यानां संकलितं व्यवकलिते प्रथमतुल्यानाम् ॥

—BrSpSi, XVIII. 41.

5. योमोऽन्तरं तेषु समानं जाल्योर्विभिन्नं जाल्योश्च प्रथक् स्थितिश्च ।

—Bhāskara II, Bijagāṇita.

This means that the numerical coefficients of x cannot be added to or subtracted from the numerical coefficients of y or x^2 or x^3 or xy and so on because these terms belong to different *jāti* or they do not belong to the category of the "like".

Again, regarding *multiplication*, Brahmagupta says :

The product of the two like unknowns is a square; the product of three or more like unknowns is a power of that designation. The multiplication of unknowns of unlike species is the same as the mutual product of symbols; it is called *bhāvita* (product or factum).¹

Having given the rules of the operations for addition, subtraction and multiplication, Brahmagupta does not think it necessary to deal with other operations. His section on the calculations with zero, negative and positive quantities ends here.

How is an Equation Formed?

Prthūdaka Svāmī while commenting on a verse in *Brahma-sphuṭasiddhānta* speaks as follows :

In this case, in the problem proposed by the questioner, *yāvat-tāvat* is put for the value of the unknown quantity. Then performing multiplication, division etc. as required in the problem the two sides shall be carefully made equal. The equation being formed in this way, then the rule (for its solution) follows.²

Plan for Writing Equations

When in regards to a given problem, an equation has been formed, it has to be written down for further operations. This writing down of an equation is technically known as *nyāsa*. Perhaps the oldest record of *nyāsa* is to be found in the *Bakhaśālī Manuscript*. According to the procedure prescribed in this work, the two sides of an equation are put down one after the other in the same line without any sign of equality being interposed. Thus the equations :

$$\sqrt{x+5}=s. \quad \sqrt{x-7}=t$$

appear as

1. सदृशद्विवधो वर्गस्यादिवधस्तद् गतोऽन्यजातिवधः ।

अन्योऽन्यवर्णघातो भावितकः पूर्ववच्छेषम् ॥

2. *BrSpSi*. XVIII. 43 (com)

—*BrSpSi*. XVIII. 42.

$$\begin{array}{|c|c|c|c|c|} \hline 0 & 5 & yu & m\bar{u} & 0 \\ \hline 1 & 1 & & & 1 \\ \hline \end{array} \quad \begin{array}{|c|c|c|} \hline sa & 0 & 7 \\ \hline 1 & 1 & \\ \hline \end{array} + \begin{array}{|c|} \hline m\bar{u} \\ \hline 0 \\ \hline \end{array}$$

Here *yu* (यु) stands for *yuta* (युत), meaning added, subtraction is + sign, derived from *Kṣaya* or (क्षय) meaning diminished, *gu* (गु) for *guṇa* or *guṇita*, meaning multiplied; *bhā* (भा) for division from *bhājita* and *mū* (मू) for square-root, from *mūla* meaning root; zero (०) was used to mark a vacant place.

Again, the following equation

$$x+2x+3\times 3x+12\times 4x=300$$

is represented as ;

$$\begin{array}{|c|c|c|c|c|c|c|} \hline 0 & 2 & 1 & 3 & 12 & 4 & \\ \hline 1 & 1 & 1 & 1 & 1 & 1 & \\ \hline \end{array} \quad dṛśya \ 300$$

There is no sign for unknown in the *Bakhaśālī Manuscript*.

Later on this plan of writing equations as adopted in *Bakhaśālī Manuscript* was abandoned in India; a new one was adopted in which the two sides are written one below the other without any sign of equality. It must be stated that in this new plan the term of similar denominations are usually written one below the other and even the terms of absent denominations on either side are clearly indicated by putting zeros as their coefficients. We find a reference to this new plan in the algebra of Brahmagupta.

From which the square of the unknown and the unknown are cleared, the known quantities are cleared (from the side) below that¹.

Here in this verse, the words "*adhastāt*" clearly indicate that one side of the equation is written below the other. As an illustration, Pṛthūdaka Svāmi represented the equation² :—

$$10x-8=x^2+1$$

as :

$$y\dot{a} \ va \ 0 \ y\dot{a} \ 10 \ r\dot{u} \ \dot{8} \quad (x^2.0+x.10-8)$$

$$y\dot{a} \ va \ 1 \ y\dot{a} \ 0 \ r\dot{u} \ 1 \quad (x^2.1+x.0+1)$$

which means, x^2 was written as *yāvat-varga* (*yā va*) and x was written as *yāvat* or *yā*. The minus sign was represented by a dot at the top of the number. (—8 was written as $\dot{8}$). We shall take another illustration from Pṛthūdaka Svāmī.

He would write the equation

$$197x-1644 \ y-z=6302$$

as

1. *BrSpSi*. XVII. 43; compare also Bhāskara II, *Bijaganita*.

2. *BrSpSi*. XVIII. 49 (*com.*)

$$\begin{array}{ccccccc} yā & 197 & kā & 1644 & nī & 1 & rū & 0 \\ yā & 0 & kā & 0 & nī & 0 & rū & 6302 \end{array}$$

Here the first unknown x is represented by $yā(vat)$, the second unknown y by $kā(laka)$ and the third unknown z by $nī(laka)$ and the term without unknown, a mere number is written by $rū(paka)$. The two sides, one written below the other if written in the present form, would appear as :

$$197x - 1644y - z + 0 = 0x + 0y + 0z + 6302.$$

The *Bijaganita* of Bhāskara II also follows the same procedure. One instance from it would be quoted here to illustrate the method of expressing equations.

$$8x^3 + 4x^2 + 10y^2x = 4x^3 + 12y^2x$$

$$\text{or } 8x^3 + 4x^2 + 10y^2x = 4x^3 + 0x^2 + 12y^2x$$

is written as follows on Bhāskara's or Brahmagupta's plan :

x^3 is *ghana* of $yāvat$ (abbreviated as $yā\ gha$)

x^2 is *varga* of $yāvat$ (abbreviated as $yā\ va$)

y^2 is *varga* of $kālaka$ (abbreviated as $kā\ va$)

the coefficients 10 and 12 are *bhāvita* (abbreviated as *bhā*).

The equation is :

$$yā\ gha\ 8\ yā\ va\ 4\ kā\ va\ yā.\ bhā\ 10$$

$$yā\ gha\ 4\ yā\ va\ 0\ kā\ va\ yā.\ bhā\ 12$$

Datta and Singh state that the use of the old plan of writing equations is sometimes met with in later works also. For instance, in the MS. of Pṛthūdaka Svāmī's commentary¹ on the *Brahmasphuṭasiddhānta*, an incomplete copy of which is preserved in the library of the Asiatic Society of Bengal (No. I B6), we find a statement of equations thus : "first side $yāvargaḥ\ 1\ yāvakāḥ\ 200\ rū\ 0$; second side $yāvargaḥ\ 0\ yāvakāḥ\ 0\ rū\ 1500$.

Śodhana or Clearance of an Equation

After *nyāsa* or statement of an equation, the operation to be performed is known as *śodhana* (clearance) or *samśodhana* (equi-clearance or complete clearance). The nature of this clearance varies according to the kind of equation. In the case of an equation in one unknown only, whether linear,

1. *BrSpSi*. XII. 15 (*com.*)

quadratic or of higher powers, one side of it is cleared of the unknowns of all denominations and the other side of it of the absolute terms, so that the equation is ultimately reduced to one of the form

$$ax^2 + bx = c,$$

where a, b, c may be positive or negative; some of them may even be zero. Thus Brahmagupta observes :

From which the square of the unknown and the unknown are cleared, the known quantities (*rūpāṇi*) are cleared (from the side) *below* that.¹

On this *Prthūdaka Svāmi* comments as follows :

This rule has been introduced for that case in which the two sides of the equation having been formed in accordance with the statement of the problem, there are present the square and other powers of the unknown together with the (simple) unknown. The absolute terms should be cleared off from the side opposite to that from which are cleared the square (and other powers) of the unknown and the (simple) unknown. When perfect clearance (*samsodhana*) has been thus made...²

Śrīdhara and *Bhāskara II* have also given the rules of clearance almost on the same lines. Thus the equation

$$yā\ va\ 0\ yā\ 10\ rā\ 8$$

$$yā\ va\ 1\ yā\ 0\ rā\ 1$$

after perfect clearance having been made will be (according to *Prthūdaka Svāmi*)

$$yā\ va\ 1\ yā\ 10\ rā\ 9$$

i.e. the equation $10x - 8 = x^2 + 1$

after clearance would become

$$x^2 - 10x = -9.$$

Classification of Equations

Usually equations are classified as :

simple equation : *yāvat-tāvat*

quadratic : *varga*

1. कर्मान्यन्ताः शोभ्या यत्माद् रूपणि तद्वस्ताद् ॥

2. *BrSpSi*. XVIII. 43 (*com.*)

cubic : *ghana*
 biquadratic : *varga-varga*

Brahmagupta classified them as

- (i) equations in one unknown quantity : *eka-varṇa samīkaraṇa*.
- (ii) equations in several unknowns : *aneka-varṇa samīkaraṇa*.
- (iii) equations involving products of unknowns : *bhāvita*.

Eka-varṇa samīkaraṇas (equations with one unknown) are further divided into (i) linear equations, and (ii) quadratic equations (*avyakta-varga samīkaraṇa*).

Prthūdaka Svāmī has classified equations in a different manner as follows :

- (i) linear equations with one unknown : *eka-varṇa samīkaraṇa*.
- (ii) linear equations with more unknowns : *aneka-varṇa samīkaraṇa*.
- (iii) equations with one, two or more unknowns in their second or higher powers : *madhyamāharaṇa*.
- (iv) equations involving products of unknowns : *bhāvita*.

As the method of solution of an equation of the third class (i.e. equations with one or several unknowns in their second or higher powers) is based upon the principle of the elimination of the middle term, that class is called by the term *madhyama* (middle) *āharaṇa* (elimination). The classification of Brahmagupta and Prthūdaka Svāmī more or less received recognition by later writers on algebra as Bhāskara II and others.

Linear Equations with One Unknown and Their Solutions

The first solution of a linear equation with one unknown is obtainable in the *Śulba Sūtras* but not through an algebraic process,—the *Śulba* process is geometrical. It is said that there is a reference in the *Sihānāṅga Sūtra* (c. 300 B.C.) to a linear equation by its name *yavat-tāvat*. There has been a good deal of

controversy regarding the date of the *Bakhaṣālī Manuscript* where we have definitely a method of solving linear equations by the *Rule of False Position*. It would be interesting to give an account of this rule here by taking an illustration from the *Bakhaṣālī Manuscript*.

Problem :

The amount given to the first is not known. The second is given twice as much as the first; the third thrice as much as the second; and the fourth four times as much as the third. The total amount distributed is 132. What is the amount of the first ?

(BMS, Folio 23, recto)

In modern algebraic language, the solution of the problem would be given by the equation

$$x + 2x + 6x + 24x = 132$$

where x is the amount given to the first.

The solution of this equation is given as follows in the *Bakhaṣālī Manuscript* :

'Putting any desired quantity in the vacant place'; any desired quantity is $\parallel 1 \parallel$, 'then construct the series'

$$\begin{array}{|c|c|c|c|c|c|c|} \hline 1 & 2 & 2 & 3 & 6 & 4 & \\ \hline 1 & 1 & 1 & 1 & 1 & 1 & \\ \hline \end{array}$$

'multiplied' $\parallel 1 \parallel 2 \parallel 6 \parallel 24 \parallel$; 'added' 33. 'Divide the visible quantity' $\parallel \begin{array}{c} 132 \\ 33 \end{array} \parallel$; which) on reduction be-

comes $\parallel \begin{array}{c} 4 \\ 1 \end{array} \parallel$. (This is) the amount given (to the first)

(BMS, Folio 23, recto)

The Rule of False Position may be regarded as an early stage of the development of the science of algebra, since no symbol could have been evolved for an unknown quantity. As soon as the system of notations was introduced, the application of this Rule was no longer considered as necessary. Thus we find that Āryabhaṭa I does not mention of this Rule.

Āryabhaṭa I states as follows regarding the solution of linear equations :

The difference of the known 'amounts' (*rūpaka*) relating to two persons should be divided by the difference

of the coefficients on the unknown (*gulikā*). The quotient will be the value of the unknown (*gulikā*), if their possessions be equal.¹

The original verse contains the term "*gulikāntara*" which has been here translated as the difference of the coefficients of the unknowns. We have already stated earlier that Āryabhaṭa uses the term *gulikā* or shot for an unknown quantity. (*gulikāntara* literally means only the difference of unknowns). This practice is also followed by other Indian algebraists. Pṛthudaka Svāmī rightly observed that according to the usual practice in this country, "the coefficient of the square of the unknown is called the square (of the unknown) and the coefficient of the (simple) unknown is called the unknown."²

The rule given by Āryabhaṭa, then, contemplates a problem of this kind :

Two persons, who are equally rich, possess respectively a, b times a certain unknown amount together with c, d units of money in cash. What is that amount ?

Now if x be the amount unknown, then according to the problem

$$ax + c = bx + d$$

Thence

$$x = \frac{d-c}{a-b}$$

Āryabhaṭa has merely expressed this solution in his language.

Regarding the solution of linear equations, Brahmagupta says :

In a (linear) equation in one unknown, the difference of the known terms taken in the reverse order, divided by the difference of the coefficients of the unknown (is the value of the unknown).³

1. गुलिकान्तरेण विभजेद् द्वयोः पुरुषयोस्तु रूपकविशेषम् ।

लब्धं गुणिकामूल्यं यद्यर्थं कृतं भवति तुल्यम् ॥

—Ārya. II. 30

2. BrSpSi, XVIII. 44 (com.)

3. अव्यक्तान्तरभवत् व्यस्तं रूपान्तरं समेऽव्यक्तः ।

वर्गाव्यक्ताः शोभ्या यस्माद् रूपाणि तदधस्तात् ॥

—BrSpSi. XVIII. 43

Similar solutions have been offered by the other Indian algebraists who followed Brahmagupta like Śrīpati, Bhāskara II and Nārāyaṇa. Here again, we take a problem proposed by Brahmagupta in this connection :

Problem :

Tell the number of elapsed days for the time when four times the twelfth part of the residual degrees increased by one, plus eight will be equal to the residual degrees plus one.¹

Prthūdaka Svāmī has solved this problem as follows :

Here the residual degrees are (put as) *yāvat-tāvat*, *yā*;
increased by one, *yā 1 rū 1*; twelfth part of it, $\frac{yā 1 rū 1}{12}$;
four times this, $\frac{yā 1 rū 1}{3}$; plus the absolute quantity
eight, $\frac{yā 1 rū 25}{3}$. This is equal to the residual degrees
plus unity. The statement of both sides tripled is

$$\begin{array}{rcl} yā 1 & rū 25 \\ yā 3 & rū 3 \end{array}$$

This difference between the coefficients of the unknown is 2. By this the difference of the absolute terms, namely 22, being divided, is produced the residual of the degrees of the Sun, 11. These residual degrees should be known to be irreducible. The elapsed days can be deduced then, (proceeding) as before.

If put in the modern notations, it means the solution of the equation :

$$\frac{4}{12} (x+1)+8=x+1,$$

from which we have

$$\begin{array}{l} x+25=3x+3 \\ \text{or} \quad 2x=22 \\ \text{or} \quad x=11. \end{array}$$

Rule of Concurrence or Saṁkramaṇa

Brahmagupta has included this rule in algebra, whereas other Indian mathematicians included it in arithmetic. *Sam-*

1. सैकादशकरोषाद् द्वादशभागश्चतुर्गुणोऽष्टयुतः ।
सैकादशकरोषतुल्यो यदा तदाऽद्वयं कथय ॥

kramana is the solution of the simultaneous equations of the type :

$$x+y=a$$

$$x-y=b$$

Brahmagupta's rule for solution is:

The sum is increased and diminished by the difference and divided by two; (the result will be the two unknown quantities): (this is) concurrence (*Samkramana*).¹

Brahmagupta restates this rule in the form of a problem and its solution :

The sum and difference of the residues of two (heavenly bodies) are known in degrees and minutes. What are the residues? The difference is both added to and subtracted from the sum, and halved; (the results are) the residues.²

Linear Equations with Several Unknowns

The first mention of a solution of the problem with more than one unknown is found in the *Bakhsāli Manuscript*, and a system of linear equations of this type is solved in the *Bakhsāli* treatise substantially by the False Position Rule.

A generalised system of linear equations will be

$$b_1 \sum x - c_1 x_1 = a_1, b_2 \sum x - c_2 x_2 = a_2, \dots, b_n \sum x - c_n x_n = a_n$$

$$b_n \sum x - c_n x_n = a_n$$

Therefore

$$\sum x = \frac{\sum(a/c)}{\sum(b/c) - 1}$$

Hence

$$x_r = \frac{b_r}{c_r} \times \frac{\sum(a/c)}{\sum(b/c) - 1} - \frac{a_r}{c_r}$$

$r=1, 2, 3, \dots, n$

One particular case, where $b_1=b_2=b_3=\dots=b_n=1$ and $c_1=c_2=c_3=\dots=c_n=c$ has been treated by Brahmagupta at one place. He gives the rule as follows :

1. योगोऽन्तरयुतहीनो द्विहृतः संक्रमणमन्तरविभक्तं वा ।

वर्गान्तरमन्तरयुतहीनं द्विहृतं विषयकर्म ॥

—*BrSpSi. XVIII. 36*

2. भागकला विकलेक्यं दृष्ट्वा विकलान्तरं च के शेषे ।

ऐक्यं द्विधाऽन्तराधिक हीनं च द्विभाजितं शेषे ॥

—*BrSpSi. XI'III. 96*

The total value (of the unknown quantities) plus or minus the individual values (of the unknowns) multiplied by an optional number being severally (given), the sum (of the given quantities) divided by the number of unknowns increased or decreased by the multiplier will be the total value; thence the rest (can be determined).¹

$$\begin{aligned}\Sigma x \pm cx_1 &= a_1, \Sigma x \pm cx_2 = a_2, \Sigma x \pm cx_3 = a_3, \dots, \\ \Sigma x \pm cx &= a_n\end{aligned}$$

Therefore

$$\Sigma x = \frac{a_1 + a_2 + a_3 + \dots + a_n}{n \pm c}$$

Hence

$$x_1 = \frac{1}{c} \left(\pm a_1 \mp \frac{a_1 + a_2 + a_3 + \dots + a_n}{n \pm c} \right);$$

and so on for x_2, x_3 etc.

Now we shall give the rule enunciated by Brahmagupta for solving linear equations involving several unknowns :

Removing the other unknowns from (the side of) the first unknown and dividing by the coefficient of the first unknown, the value of the first unknown (is obtained). In the case of more (values of the first unknown), two and two (of them) should be considered after reducing them to comon denominators. And (so on) repeatedly. If more unknowns remain (in the final equation), the method of the pulveriser (should be employed). (Then proceeding) reversely (the values of other unknowns can be found).²

Prthudaka Svāmī has commented on this rule as follows :

In an example in which there are two or more unknown quantities, colours such as *yāvat-tāvat*, etc., should be assumed for their values. Upon them should

1. गच्छधनमिष्ट गुणितैर्धनैर्धु तोनं पृथक् पृथक् सहितम् ।

गुणकयुतेन पदहतं सर्वधनमतोऽवशेषाणि ॥

—BrSpSi. XIII. 47

2. आधादकर्णान्यान् वर्णान् प्रो ह्यिहमानमाद्यहतम् ।

सदशब्देदाक्सकृद् द्वौ व्यस्तौ कुट्टको बहुषु ॥

—BrSpSi. XVIII. 51

be performed all operations conformably to the statement of the example and thus should be carefully framed two or more sides and also equations. Equi-clearance should be made first between two and two of them and so on to the last : from one side one unknown should be cleared, other unknowns reduced to a common denominator and also the absolute numbers should be cleared from the side opposite. The residue of other unknowns being divided by the residual coefficient of the first unknown will give the value of the first unknown. If there be obtained several such values, then with two and two of them, equations should be formed after reduction to common denominators. Proceeding in this way to the end find out the value of one unknown. If that value be (in terms of) another unknown then the coefficients of those two will be reciprocally the values of the two unknowns. If, however, there be present more unknowns in that value, the method of the pulveriser should be employed. Arbitrary values may then be assumed for some of the unknowns.

Datta and Singh have said that the above rule of Brahmagupta, and also the one indicated in the commentary of Pṛthudaka Svāmī, embraces the solution of indeterminate as well as the determinate equations. In fact, all the examples given by Brahmagupta in illustration of the rule are of indeterminate character. So far as the determinate simultaneous equations are concerned, Brahmagupta's method for solving them will be easily recognised to be the same as our present one.

Quadratic Equations

The geometrical solution of a quadratic equation in this country would take us to the Vedic Śulba period. The *Bakṣasāli Manuscript* also contains certain problems which need the solving of quadratic equations. I shall quote one out of the numerous available :

A certain person travels s *yojana* on the first day and b *yojana* more on each successive day. Another, who travels at the uniform rate of S *yojana* per day, has a start of t days. When will the first man overtake the second ?

This problem would today be expressed in terms of the following equation :

$$S(t+x)=x\left\{s+\left(\frac{x-1}{2}\right)b\right\},$$

where x is the number of days after which the first overtakes the second. We may write this equation as

$$bx^2 - \{2(S-s)+b\}x = 2tS$$

whence the value x would be after solving the quadratic :

$$x = \frac{\sqrt{\{2(S-s)+b\}^2 + 8bts} + \{2(S-s)+b\}}{2b}$$

The *Bakhasālī Manuscript* gives this solution as follows :

The daily travel (S) diminished by the march of the first day (s) is doubled; this is increased by the common increment (b). That (*sum*) multiplied by itself is designated (as the *kṣepa* quantity). The product of the daily travel and the start (t) being multiplied by eight times the common increment, the *kṣepa* quantity is added. The square-root of this (is increased by the *kṣepa* quantity; the sum divided by twice the common increment will give the required number of days). (BMS. Folio 5, recto)

Āryabhaṭa I (499 A.D.) is regarded as the founder of algebra, since he gives the solutions of a few quadratic problems. For example, to find the number of terms of an arithmetical progression (A.P.), he gives the following rule :

The sum of the series multiplied by eight times the common difference is added by the square of the difference between twice the first term and the common difference: the square-root (of the result) is diminished by twice the first term and (then) divided by the common difference : half of this quotient plus unity is the number of terms.¹

In the modern notations of algebra, the solution would be expressed as follows :

1. यच्छोऽष्टोत्तर गुणितान् द्विगुणाद्युत्तर विशेषकान्युतात् ।

मूलं द्विगुणाद्युत्तरं स्वोत्तरं भजितं सरूपार्थं ॥

$$n = \frac{1}{2} \left\{ \frac{\sqrt{8bs + (2a-b)^2} - 2a}{b} + 1 \right\}$$

There is another certain interest problem¹, the solution of which has been provided in the *Āryabhaṭīya* as

$$x = \frac{\sqrt{Apt + (p/2)^2} - p/2}{t}$$

which is the solution of the quadratic equation :

$$tx^2 + px - Ap = 0$$

Āryabhaṭa I has thus given the solutions of a few quadratic equations, but he nowhere gives the procedure of solving these equations.

We give here the Rules of Brahmagupta for the solution of quadratic equations. He undoubtedly is not the discoverer of these rules; but perhaps for the first time in the history of algebra we find the process of solving a quadratic equation so clearly indicated.

First Rule :

The quadratic : the absolute quantities multiplied by four times the coefficient of the square of the unknown are increased by the square of the coefficient of the middle (i.e. unknown); the square-root of the result being diminished by the coefficient of the middle and divided by twice the coefficient of the square of the unknown, is (the value of) the middle.”²

This expressed in the modern notations would mean

$$x = \frac{\sqrt{4ac + b^2} - b}{2a}$$

It would be noted that in this rule, Brahmagupta has employed the term *madhya* (middle) to imply the simple unknown as well as its coefficient. The origin of the term is doubtless connected with the mode of writing the quadratic equation in the form

$$ax^2 + bx + 0 = 0x^2 + 0x + c$$

so that there are three terms on each side of the equation.

1. मूलफलं सफलं कालमूलं गुणमर्धमूलं कृति युक्तम् ।

मूलं मूलार्धेन कालद्वते स्यात्स्वमूलफलम् ॥

—*Ārya. II. 25.*

2. वर्गं चतुर्गुणितानां रूपाणां मध्यवर्गसहितानाम् ।

मूलं मध्येनोर्ध्वं वर्गं द्विगुणोद्धृतं मध्यः ॥

—*BrSpSi. XVIII. 44.*

Second Rule :

The absolute term multiplied by the coefficient of the square of the unknown is increased by the square of half the coefficient of the unknown; the square-root of the result diminished by half the coefficient of the unknown and divided by the coefficient of the square of the unknown is the unknown.²

This when expressed in the modern algebraic notations would be

$$x = \frac{\sqrt{ac + (b/2)^2} - (b/2)}{a}$$

Here if the quadratic equation is

$$ax^2 + bx + c = 0$$

the 'absolute term' is c (the one without the unknown x), 'the coefficient of the square of unknown' means the coefficient of x^2 , i.e. a , and the 'coefficient of the unknown' means the coefficient of x , i.e. b .

The above two methods of Brahmagupta are exactly the same as were suggested by Āryabhaṭa I.

The root of the quadratic equation for the number of terms of an arithmetic progression (A.P.) is given by Brahmagupta according to the first rule² :

$$n = \frac{\sqrt{8bs + (2a - b)^2} - (2a - b)}{2b}$$

Third Rule :

Brahmagupta also suggests a Third Rule which is very much the same as is used commonly now. Though it has not been expressly suggested as a new rule, we find its application in a few instances. For example this rule has been suggested in connection with the following problem on interest :

A certain sum (p) is lent out for a period (t_1); the interest accrued (x) is lent out again at this

1. वर्गादित रूपाणामव्यक्तार्थकृति संयुतानां यत् ।

पदमव्यक्तार्थोनं तद्वर्गं विभक्तमव्यक्तः ॥

—BrSpSi. XVIII. 45

2. उत्तरहीनदिगुणादि शेषवर्गं धनोत्तराष्टवषे ।

—BrSpSi. XII. 18

rate of interest for another period (t_2) and the total amount is A . Find x .

The equation for determining x is

$$\frac{t_2}{pt_1}x^2 + x = A.$$

The solution of this equation would be :

$$x = \sqrt{\left(\frac{pt_1}{2t_2}\right)^2 + \frac{A}{t_2}} - \frac{pt_1}{2t_2}$$

Brahmagupta has stated the result in exactly the same form. Pṛthudaka Svāmī has illustrated it in solving the following problem of interest :

Problem :

A sum of five hundred *paṇas* (p) is lent out for a period of 4 months (t_1); the interest accrued (x) is lent out again at this rate of interest for another period of 10 months (t_2) and the total amount is 78 (A). Give the *pramāṇa-phala*, i.e., the interest accrued x .

Here *pramāṇa-kāla* (t_1) = 4 months

pramāṇa-dhana (p) = 500 *paṇas*

para-kāla (t_2), the subsequent period = 10 months

miśra dhana or the total interest accrued (A) = 78 *paṇas*.

Brahmagupta states his solution of such quadratics like this :

Take the product of the *pramāṇa-dhana* (p) or the sum originally lent out and *pramāṇa-kāla*, i.e. the period for which originally lent out (t_1); and divide by the *para-kāla* or the subsequent time (t_2); place this result at two places. Multiply the one placed at the first place with the *miśra-dhana* (A), that is with the total interest accrued; in this product add the square of half the one placed in the second place; now take the square-root of it, and from it subtract half of the one placed at the second place.¹

1. कालप्रमाणधनः परकालहतो दिवाऽऽवमिश्रधनात् ।

अन्यार्धकृति युतात् पदमन्यार्धेन प्रमाण फलम् ॥

—BrSpSi. XII. 15:

Thus in the above example the product of *pramāṇa-dhana* and *pramāṇa kālā* divided by *parakālā* is (pt_1/t_2) is $\frac{500 \times 4}{10} = 200$.

This is first multiplied by the 'total' interest accrued (A); it becomes $200 \times 78 = 15600$. To this is now added square of half of 200 (which is 10000); it becomes 15600 plus 10000 = 25600. Its square-root is taken which is 160. From this is subtracted half of the quantity (i.e. half of 200 which is 100). Thus $160 - 100 = 60$, which is the answer. It was the interest which first accrued (x).

... *Another Quadratic Problem:*

Brahmagupta refers to an astronomical problem which involves the quadratic equation

$$(72 + a^2)x^2 \mp 24apx = 144\left(\frac{R^2}{2} - p^2\right),$$

where $a = \text{agra}$ (the sine of the amplitude of the Sun), $b = \text{palabha}$ (the equinoctial shadow of a gnomon 12 anguli long), $R = \text{radius}$, and $x = \text{koṇasāṅku}$ (sine of the altitude of the Sun when his altitude is 45°). Dividing out by $(72 + a^2)$ we have

$$x^2 \mp 2mx = n,$$

where

$$m = \frac{12ap}{72 + a^2}, \quad n = \frac{144(R^2/2 - p^2)}{72 + a^2}.$$

Therefore we have

$$x = \sqrt{m^2 + n} \pm m,$$

as stated by Brahmagupta. We find the same result in the *Sūrya-siddhānta* and in the text of Śrīpati. Āryabhaṭa II (1150) also followed the method of Āryabhaṭa I and Brahmagupta in solving a quadratic equation in connection with finding out the number of terms in an arithmetical progression (A.P.) whose first term is (a) , common difference is b and the sum is s . The number of terms n is given by¹

$$n = \frac{\sqrt{2bs + (a - b/2)^2} - a + b/2}{b}$$

Two Roots of a Quadratic Equation and Brahmagupta

A quadratic equation has two roots. This must have been known to Indian algebraists even at a very early stage. Bhāskara II in his *Bījaganita* has quoted a rule ascribed to an ancient writer Padmanābha whose works are not available now :

1. *Mahāsiddhānta*. Bhāskara II, XV. 50

If (after extracting roots) the square-root of the absolute side (of the quadratic) be less than the negative absolute term on the other side, then taking it negative as well as positive two values (of the unknown) are found¹.

The term used here is *dvividhotpadyate mitih* which means that two values are obtained.

The existence of two roots of a quadratic equation appears to have been known also to Brahmagupta (628 A.D.). In illustration of his rules for the solution of a quadratic he has stated two problems involving practically the same equation :

Problem I : The square-root of the residue of the revolution of the Sun less 2 is diminished by 1, multiplied by 10 and added by 2; when will this be equal to the residue of the revolution of the Sun less 1, on Wednesday ?²

Problem II : When will the square of one-fourth the residue of the exceeding months less three, be equal to the residue of the exceeding months ?

We shall follow Prthūdaka Svāmi in solving the Problem I. In this problem the residue of the revolutions of the Sun may be supposed to be x^2+2 ; then by the question, we have

$$10(x-1)+2=x^2+1, \\ \text{or } x^2-10x=-9$$

Again in Problem II, if we put $4x$ for the residue of the exceeding month, then we have

$$(x-3)^2=4x \\ \text{or } x^2-10x=-9,$$

Now by the second rule of Brahmagupta, retaining both the signs of the radical, we get :

$$x=5\pm\sqrt{25-9}=9 \text{ or } 1,$$

1. व्यक्त पक्षस्य चैन्मूलमन्यपक्षार्थरूपतः ।

अल्पं धनर्यगं कृत्वा द्विविधोत्पद्यते मितिः ॥

—Bhāskara, *Bījaganita*

2. मण्डलशेषाद् द्रव्यनाम्नूलं व्येकं दशाहृतं द्रियुतम् ।

मण्डलशेषं व्येकं भानोर्द्विदिने कदा भवति ॥

—BrSpSi. XVIII. 49

3. अधिमासशेषपादात् व्यूनाद्वर्गोऽधिमासशेषसमः ।

अवंमावर्शेषतो वाक्यशेषसमः कदा भवति ॥

—BrSpSi. XVIII. 50.

As shown by Pṛthudaka Svāmī, the first value is taken by Brahmagupta for the Problem I and second value for the problem II. Thus it is quite clear that Brahmagupta uses sometimes the positive and at other times the negative sign with the radical. Hence we shall say that Brahmagupta knew that a quadratic equation would have two roots, and according to the requisiteness of the problem, one value out of the two would be utilised.

Simultaneous Quadratic Equations

Indian authors usually treated problems involving various forms of simultaneous quadratic equations.

$$\begin{array}{ll} \text{(i)} \quad \left. \begin{array}{l} x-y=d \\ xy=b \end{array} \right\} & \text{(ii)} \quad \left. \begin{array}{l} x+y=a \\ xy=b \end{array} \right\} \\ \text{(iii)} \quad \left. \begin{array}{l} x^2+y^2=c \\ xy=b \end{array} \right\} & \text{(iv)} \quad \left. \begin{array}{l} x^2+y^2=c \\ x+y=a \end{array} \right\} \end{array}$$

For the solution of the combination (i), Āryabhaṭa I gives the following rule in his *Āryabhaṭīya*.

The square-root of four times the product (of two quantities) added with the square of their difference, being added and diminished by their difference and halved gives the two multiplicands.¹

This means that

$$x = \frac{1}{2} \sqrt{d^2 + 4b} + d, \quad y = \frac{1}{2} (\sqrt{d^2 + 4b} - d)$$

For the solution of the same combination, Brahmagupta states as follows :

The square-root of the sum of the square of the difference of the residues and two squared times the product of the residues, being added and subtracted by the difference of the residues, and halved (gives) the desired residues severally.²

(Here by difference of the residues is meant $x-y$; and by product of the residues is meant xy .)

Brahmagupta does not seem to give the solution for simultaneous equations of the combination (ii). Mahāvīra (850 A.D.)

1. द्विकृति गुणात्संवर्गाद् द्वयन्तरवर्गेण संयुतान्मूलम् ।

अन्तरयुक्तं हीनं तद्गुणकारद्वयं दलितम् ॥

—Ārya. II. 24

2. शेषवद् द्वि कृति गुणात् शेषान्तरं कर्त्तुं संयुतान्मूलम् ।

शेषान्तरेण युक्तं दलितं शेषे पृथगभीष्टे ॥

—Br SpSi. XVIII. 99

has given the solution :

Subtract four times the area (of a rectangle) from the square of the semi-perimeter then by *sankramana* between the square-root of that (remainder) and the semi-perimeter, the base and the upright are obtained.¹ (GSS. VII. 129 $\frac{1}{2}$)

This expressed in the modern notations would be :

$$x = \frac{1}{2}(a + \sqrt{a^2 - 4b}), y = \frac{1}{2}(a - \sqrt{a^2 - 4b})$$

For the combination (iii), Mahāvīra in his *Ganita-Sāra-Saṃgraha* gives the following rule :

Add to and subtract twice the area (of a rectangle) from the square of the diagonal and extract the square-roots. By *sankramana* between the greater and lesser of these (roots), the side and upright (are found).²

This put in modern notations would be :

$$x = \frac{1}{2}(\sqrt{c+2b} + \sqrt{c-2b}),$$

$$y = \frac{1}{2}(\sqrt{c+2b} - \sqrt{c-2b}).$$

For the combination (iv), Āryabhaṭa I gives the following rule :

From the square of the sum (of two quantities) subtract the sum of their squares. Half of the remainder is their product.³

The remaining operations will be similar to those for the equations (ii); so that

$$x = \frac{1}{2}(a + \sqrt{2c - a^2}), y = \frac{1}{2}(a - \sqrt{2c - a^2}).$$

Brahmagupta in this connection says :

Subtract the square of the sum from twice the sum of squares; the square-root of the remainder being added to and subtracted from the sum and halved, (gives) the desired residues.⁴

2. GSS. VII. 127 $\frac{1}{2}$

3. संपर्कस्य हि वर्गाद्विशोधयेदेव कर्तव्यं ।

यत्तस्य भवत्यर्थं विवादं गुणकारसंघर्षम् ॥

4. कृति संयोगाद् दिगुणाद्युति कर्त्तव्यं प्रोक्तं शेष मूलं यत् ।

तेन युक्तो योगो दलितः शेषे पृथगभीष्टे ॥

—Ārya. II. 23

—BrSpSi. XVIII. 98

These equations have also been treated by Mahāvīra, Bhāskara II and Nārāyaṇa. Nārāyaṇa has attempted two other forms of quadratic equations :

$$(v) \begin{cases} x^2 + y^2 = c \\ x - y = d \end{cases} \quad (vi) \begin{cases} x^2 - y^2 = m \\ xy = b \end{cases}$$

For their solutions, see Datta and Singh, *Algebra*, P. 84.

Rule of Dissimilar Operations :

Datta and Singh say that the process of solving the following two particular cases of simultaneous quadratic equations was distinguished by most Indian mathematicians by the special designation *viśama-karma* or dissimilar operation :

$$(i) \begin{cases} x^2 - y^2 = m \\ x - y = n \end{cases} \quad (ii) \begin{cases} x^2 - y^2 = m \\ x + y = p \end{cases}$$

These equations have been regarded by these mathematicians as if of fundamental importance. They have given the following solutions (expressed in modern algebraic symbols) :

For the combination (i) :

$$x = \frac{1}{2} \left(\frac{m}{n} + n \right), \quad y = \frac{1}{2} \left(\frac{m}{n} - n \right),$$

For the combination (ii) :

$$x = \frac{1}{2} \left(p + \frac{m}{p} \right), \quad y = \frac{1}{2} \left(p - \frac{m}{p} \right).$$

We shall express these solutions as follows in the words of Brahmagupta :

The difference of the squares (of the unknowns) is divided by the difference of the unknowns and the quotient is increased and diminished by the difference and divided by two ; (the results will be the two unknown quantities) ; (this is) dissimilar operation.

The same rule is restated by him on a different occasion in the course of solving a problem.

If then the difference of their squares, also the difference of them (are given) ; the difference of the squares

1. योगोऽन्तरयुतहीनो दिह्यतः संक्रमणमन्तर विभक्तं वा ।
२. योऽन्तरमन्तरयुतहीनं दिह्यतं विषमकर्म ।

is divided by the difference of them, and this (latter) is added to and subtracted from the quotient and then divided by two ; (the results are) the residues whence the number of elapsed days (can be found).¹

This *viṣama-karma* or dissimilar operation has been described by other Indian algebraists also, as Āryabhaṭa II (*Mahāśi-
ddhantā*, XVII, 22); Śrīpati (*Siddhantā-sekhara*, XIV, 13); Bhā-
skara II (*Līlavatī*) and Nārāyaṇa (*Gaṇita-kaumudī*, I, 32).

Indeterminate Equations of the First Degree

Āryabhaṭa I should be given the credit of giving for the first time a treatment of the indeterminate equation of the first degree. In his *Āryabhaṭīya*, we find a method for obtaining the general solution in positive integers of the simple indeterminate equation :

$$by - ax = c$$

for integral values of a, b, c , and further indicated how to extend it to get positive integral solutions of simultaneous indeterminate equations of the first degree. His disciple Bhāskara I (522) showed that the same method might be applied to solve :

$$by - ax = -c$$

and further that the solution of this equation would follow that of $by - ax = -1$. These methods of Āryabhaṭa I and Bhāskara I have also been adopted by Brahmagupta, and in certain cases, the improvement were suggested by Āryabhaṭa II in the middle of the tenth century A.D.

The problems which were treated by ancient Indian algebraists and which led them to the investigation of the simple indeterminate equation of the first degree may be classified under three heads :

Class I : To find a number N which being divided by two given numbers (a, b) will leave two given remainders (R_1, R_2).

Thus we have :

$$N = ax + R_1 = by + R_2$$

1. तद्वर्गान्तरमाद्ये तदन्तरं चान्तरोदधृतयुतोन्म ।
वर्गान्तरं विभक्तं द्वान्यां शेषे ततोद्युगलः ।

Hence $by - ax = R_1 - R_2$

Putting $c = R_1 \cup R_2$

we get $by - ax = \pm c$

the upper or lower sign being taken according as R_1 is greater than or less than R_2 .

Class II : To find a number (x) such that its product with a given number (a) being increased or decreased by another given number (δ) and then divided by a third given number (β) will leave no remainder.

This means that in other words, we shall have to get the solution of :

$$\frac{ax \pm r}{\beta} = y$$

in positive integers.

Class III : Here we have to deal with an equation of the form :

$$by \div ax = \pm c$$

Kuṭṭaka, *Kuṭṭākāra* and *Kuṭṭa* : These are the three terms which Brahmagupta has used in regards to the subject of indeterminate analysis of the first degree. Āryabhaṭa I has also described this method in brief, but he does not use the word *kuṭṭaka*. In the *Mahābhāskariya* of Bhāskara I we have the terms *kuṭṭākāra* and *kuṭṭa* (522 A.D.) MBh. I. 41.49). These words have been translated into English as *pulveriser* or *grinder*. According to Datta and Singh, the Hindu method of solving the equation $by - ax = \pm c$ is essentially based on a process of deriving from it successively other similar equations in which the values of the coefficients (a, b) become smaller and smaller. Thus the process is indeed the same as that of breaking a whole thing into smaller pieces, and this accounts for its name *kuṭṭaka* or '*pulveriser*'.

In the problems of the Class I, the quantities (a and b) are called 'divisors' (*bhāgahāra*, *bhājaka*, *cheda* etc.) and R_1 and R_2 as 'remainders' (*agra* or *śeṣa* etc.). while in a problem of the Class II ; β is ordinarily called the 'divisor' (*bhāgahāra* or *bhājaka*) and γ the 'interpolator' (*kṣepa*, *kṣepaka* etc.) ; here a is called the 'dividend' (*bhājya*), the unknown quantity to be found (x) is called the 'multiplier' or (*gunaka* or *gunakāra* etc) and y the

quotient or *phala*. In later years, Mahāvīra has called the unknown number (x) as *rāsi*.

Preliminary Operations in Kuṭṭaka-Karma

Usually it has been suggested that in order that an equation of the form

$$by - ax = \pm c \text{ or } by + ax = \pm c$$

may be amenable to solution, the two numbers a and b must not have a common divisor; for otherwise, the equation would be absurd, unless the number c had the same common divisor. So before the rules which we shall give hereafter, could be applied, the numbers a, b, c must be made prime (*dydha* or firm; *niccheda* or having no divisor, or *nirapavarta*, meaning irreducible to each other.

In this connection Bhāskara I writes :

The dividend and divisor will become prime to each other on being divided by the residue of their mutual division. The operation of the pulveriser should be considered in relation to them.¹

Similarly we find in the writings of Brahmagupta :

Divide the multiplier and the divisor mutually and find the last residue; those quantities being divided by the residue will be prime to each other.²

Āryabhaṭa's Rule : Āryabhaṭa I is probably the first Indian writer on this subject, but the operation given by him is rather obscure. His disciple Bhāskara I has given the solution of indeterminate equations of the first degree in more satisfactory language. We shall give here the translation of Āryabhaṭa's verse from the *Āryabhaṭaśāstra*, as rendered by Bibhutibhusan Datta, because other translations of this verse do very often confuse the sense :

Divide the divisor corresponding to the greater remainder by the divisor corresponding to the smaller remain-

1. भूदिनेष्टयस्यान्योऽन्य भक्तशेषेण भाजितौ ।

हारभाज्यौ ह्रदौ स्वातां कुट्टाकारं तदोर्विदुः

2. हतयोः परस्परं यच्चेषं गुणकारभागहारकयोः ।

तेन हतौ निश्चेदौ तावेव परस्परं हतयोः ।

—MBh, I. 41

—BrSpSi. XVIII. 9.

Hence ' $by - ax = R_1 - R_2$

Putting $c = R_1 \cup R_2$

we get $by - ax = \pm c$

the upper or lower sign being taken according as R_1 is greater than or less than R_2 .

Class II : To find a number (x) such that its product with a given number (a) being increased or decreased by another given number (δ) and then divided by a third given number (β) will leave no remainder.

This means that in other words, we shall have to get the solution of :

$$\frac{ax \pm r}{\beta} = y$$

in positive integers.

Class III : Here we have to deal with an equation of the form :

$$by \div ax = \pm c$$

Kuṭṭaka, *Kuṭṭākāra* and *Kuṭṭa* : These are the three terms which Brahmagupta has used in regards to the subject of indeterminate analysis of the first degree. Āryabhaṭa I has also described this method in brief, but he does not use the word *kuṭṭaka*. In the *Mahābhāskariya* of Bhāskara I we have the terms *kuṭṭākāra* and *kuṭṭa* (522 A.D.) MBh. I. 41,49). These words have been translated into English as *pulveriser* or *grinder*. According to Datta and Singh, the Hindu method of solving the equation $by - ax = \pm c$ is essentially based on a process of deriving from it successively other similar equations in which the values of the coefficients (ab) become smaller and smaller. Thus the process is indeed the same as that of breaking a whole thing into smaller pieces, and this accounts for its name *kuṭṭaka* or '*pulveriser*'.

In the problems of the Class I, the quantities (a and b) are called 'divisors' (*bhāgahāra*, *bhājaka*, *cheda* etc.) and R_1 and R_2 as 'remainders' (*agra* or *śeṣa* etc.). while in a problem of the Class II; β is ordinarily called the 'divisor' (*bhāgahāra* or *bhājaka*) and γ the 'interpolator' (*kṣepa*, *kṣepaka* etc.); here a is called the 'dividend' (*bhājya*), the unknown quantity to be found (x) is called the 'multiplier' or (*gunaka* or *gunākāra* etc) and y the

quotient or *phala*. In later years, Mahāvīra has called the unknown number (x) as *rāsi*.

Preliminary Operations in Kuṭṭaka-Karma

Usually it has been suggested that in order that an equation of the form

$$by - ax = \pm c \text{ or } by + ax = \pm c$$

may be amenable to solution, the two numbers a and b must not have a common divisor; for otherwise, the equation would be absurd, unless the number c had the same common divisor. So before the rules which we shall give hereafter, could be applied, the numbers a, b, c must be made prime (*dr̥ḍha* or firm; *niccheda* or having no divisor. or *nirapavarta*, meaning irreducible to each other.

In this connection Bhāskara I writes :

The dividend and divisor will become prime to each other on being divided by the residue of their mutual division. The operation of the pulveriser should be considered in relation to them.¹

Similarly we find in the writings of Brahmagupta :

Divide the multiplier and the divisor mutually and find the last residue; those quantities being divided by the residue will be prime to each other.²

Āryabhaṭa's Rule : Āryabhaṭa I is probably the first Indian writer on this subject, but the operation given by him is rather obscure. His disciple Bhāskara I has given the solution of indeterminate equations of the first degree in more satisfactory language. We shall give here the translation of Āryabhaṭa's verse from the *Āryabhaṭīya*, as rendered by Bibhutibhusan Datta, because other translations of this verse do very often confuse the sense :

Divide the divisor corresponding to the greater remainder by the divisor corresponding to the smaller remain-

1. भूदिनेष्टगणान्योन्य भक्तशेषेण भाजितौ ।

हारभाज्यौ ददौ स्वातां कुट्टाकारं तबोर्विदुः

2. हृतयोः परस्परं यच्छेषं गुणकारभागहारकयोः ।

तेन हृतौ निश्छेदौ तावेव परस्परं हृतयोः ।

—BrSpSi. XVIII. 9.

der. The residue (and the divisor corresponding to the smaller remainder) being mutually divided, the last residue should be multiplied by such an optional integer that the product being added (in case the number of quotients of the mutual division is even) or subtracted (in case the number of quotients is odd) by the difference of the remainders (will be exactly divisible by the last but one remainder. Place the quotients of the mutual division successively one below the other in a column; below them the optional multiplier and underneath it the quotient just obtained). Any number below the penultimate) is multiplied by the one just above it and then added by that just below it. Divide the last number (obtained by doing so repeatedly) by the divisor corresponding to the smaller remainder; then multiply the residue by the divisor corresponding to the greater remainder and add the greater remainder. (The result will be) the number corresponding to the two divisors.¹

There is an alternative rendering of this passage also as follows :

Divide the divisor corresponding to the greater remainder by the divisor corresponding to the smaller remainder. The residue (and the divisor corresponding to the smaller remainder) being mutually divided (until the remainder becomes zero), the last quotient should be multiplied by an optional integer and then added (in case the number of quotients of the mutual division is even) or subtracted (in case the number of quotients is odd) by the difference of the remainders. (Place the other quotients of mutual division successively one below the other in a column; below them the result just obtained and underneath it the optional integer). Any

1. अधिकप्रभागहारं द्विन्वाद्नाप्रभागहारेण ।

अथ उपरि गुणितमन्ययुगूनाञ्छेद भाजिते शेषम् ।

अधिकप्रश्नद्वयं द्विच्छेदाप्रमधिकप्रयुतम् ।

number below (i.e. the penultimate) is multiplied by the one just above it and then added by that just below it. Divide the last number (obtained by doing so repeatedly) by the divisor corresponding to the smaller remainder; then multiply the residue by the divisor corresponding to the greater remainder and add the greater remainder. (The result will be) the number corresponding to the two divisors.

Āryabhata's problem may be enunciated thus :

To find a number (N) which being divided by two given numbers (a, b) will leave two given remainders (R_1, R_2).

This gives :

$$N = ax + R_1 = by + R_2$$

(where R_1 is a greater remainder and R_2 lesser remainder, and a is the divisor corresponding to greater remainder and b the divisor corresponding to the lesser remainder.)

Denoting as before by c the difference between R_1 and R_2 , we get

$$(i) \quad by = ax + c, \text{ if } R_1 > R_2$$

$$(ii) \quad ax = by + c, \text{ if } R_2 > R_1$$

the equation being so written as to keep c always positive.

Hence the problem now reduces to making either

$$\frac{ax+c}{b} \text{ or } \frac{by+c}{a}$$

according as $R_1 > R_2$ or $R_2 > R_1$, a positive integer. So Āryabhata says : Divide the divisor corresponding to the greater remainder etc."

Now we shall proceed with the details of the operation as proposed by Datta and Singh in his *History of Hindu Mathematics, Part II. Algebra* :

Suppose $R_1 > R_2$; then the equation to be solved will be

$$ax + c = by \quad \dots(i)$$

a, b being prime to each other.

Let

$$\begin{array}{r}
 b) \ a \ (q \\
 \quad bq \\
 \hline
 \quad r_1) \ b \ (q_1 \\
 \quad \quad r_1 q_1 \\
 \hline
 \quad \quad r_2) \ r_1 \ (q_2 \\
 \quad \quad \quad r_2 q_2 \\
 \hline
 \quad \quad \quad r_3 \\
 \quad \quad \quad \dots \\
 \hline
 \quad \quad \quad r_{m-1}) \ r_{m-2} \ (q_{m-1} \\
 \quad \quad \quad \quad r_{m-1} \ q_{m-1} \\
 \hline
 \quad \quad \quad \quad r_m) \ r_{m-1} \ (q_m \\
 \quad \quad \quad \quad \quad r_m q_m \\
 \hline
 \quad \quad \quad \quad \quad r_m + 1
 \end{array}$$

Then we get (when $a < b$, we shall have $q=0$, $r_1=a$)

$$\begin{aligned}
 a &= bq + r_1 \\
 b &= r_1 q_1 + r_2 \\
 r_1 &= r_2 q_2 + r_3 \\
 r_2 &= r_3 q_3 + r_4 \\
 &\dots \quad \dots \quad \dots \\
 r_{m-2} &= r_{m-1} q_{m-1} + r_m \\
 r_{m-1} &= r_m q_m + r_m + 1
 \end{aligned}$$

Now, substituting the value of a in the given equation (1), we get

$$by = (bq + r_1)x + c$$

Therefore

$$y = qx + y_1$$

where

$$by_1 = r_1 x + c$$

In other words, since $a = bq + r_1$, on putting

$$y = qx + y_1 \tag{ii}$$

the given equation (i) reduces to

$$by_1 = r_1 x + c \tag{iii}$$

Again, since $b = r_1 q_1 + r_2$

putting similarly $x=q_1y_1+x_1$

the equation (iii) can be further reduced to

$$r_1x_1=r_2y_1-c \quad (\text{iv})$$

and so on.

Writing down the successive values and reduced equations in columns, we have

(1) $y=qx+y_1$	(I.1) $by_1=r_1x+c$
(2) $x=qy_1+x_1$	(I.2) $r_1x_1=r_2y_1-c$
(3) $y_1=q_2x_1+y_2$	(I.3) $r_2y_2=r_3x_1+c$
(4) $x_1=q_3y_2+x_2$	(I.4) $r_3x_2=r_4y_2-c$
(5) $y_2=q_4x_2+y_3$	(I.5) $r_4y_3=r_5x_2+c$
(6) $x_2=q_5y_3+x_3$	(I.6) $r_5x_3=r_6y_3-c$
.....
(2n-1) $y_{n-1}=q_{2n-2}x_{n-1}+y_n$	(I. 2n-1) $r_{2n-2}y_n=r_{2n-1}x_{n-1}+c$
(2n) $x_{n-1}=q_{2n-1}y_n+x_n$	(I. 2n) $r_{2n-1}x_n=r_{2n}y_n-c$
(2n+1) $y_n=q_{2n}x_n+y_{n+1}$	(I. 2n+1) $r_{2n}y_{n+1}=r_{2n+1}x_n+c$

Now the mutual division can be continued either (i) to the finish or (ii) so as to get a certain number of quotients and then stopped. In either case the number of quotients found, neglecting the first one (q), as is usual with Āryabhaṭa, may be even or odd.

Case (i) First suppose that the mutual division is continued until the zero remainder is obtained. Since a , b are prime to each other, the last one remainder is unity.

Subcase (i.1). Let the number of quotients be even. We then have

$$r_{2n}=1, r_{2n-1}=0, q_{2n}=r_{2n-1}$$

The equations (1,2n) and (I.2n+1), therefore become

$$y_n=q_{2n}x_n+c$$

and

$$y_{n+1}=c$$

respectively. Giving an arbitrary integral value (t) to x_n we get an integral value of y_n . From that we can find the value of x_{n-1} by the equation (2n). Proceeding backwards step by step we ultimately find the values of x and y in positive integers. So that the equation (I) is solved.

Subcase (i. 2) : If the number of quotients be odd, we shall have

$$r_{2n-1}=1, r_{2n}=0, q_{2n-1}=r_{2n-2}.$$

The equations $(2n+1)$ and $(I. 2n+1)$ will then be absent and the equations $(I. 2n-1)$ and $(I. 2n)$ will be reduced respectively to

$$x_{2n-1} = q_{2n-1} y - c$$

and $x_n = -c$

Giving an arbitrary integral value (t') to y_n we get an integral value of x_{n-1} . Then proceeding backwards as before we calculate the values of x and y .

Case (ii) : Next suppose that the mutual division is stopped after having obtained an even or odd number of quotients.

Subcase (ii.1) : If the number of quotients obtained be *even* the reduced form of the original equation is

$$r_2 y + 1 = r_{2n} + 1 x_n + c$$

$$\text{or } y_n + 1 = \frac{r_{2n} + 1 x_n + c}{r_2}$$

Giving a suitable integral value (t) to x_n as will make

$$y_n + 1 = \frac{r_{2n} + 1 t + c}{r_{2n}} = \text{an integral number,}$$

we get an integral value for y_n by $(2n+1)$. The values of x and y can then be calculated by proceeding as before.

Subcase (ii.2) : If the number of quotients be *odd* the reduced form of the quotient is

$$r_{2n-1} x_n = r_{2n} y_n - c$$

$$\text{or } x_n = \frac{r_{2n} y_n - c}{r_{2n-1}}$$

Putting $y_n = t'$, where t' is an integer, such that

$$x_n = \frac{r_{2n} t' - c}{r_{2n-1}} = \text{a whole number,}$$

we get an integral value of x_{n-1} by $(2n)$. Whence can be calculated the values of x and y in integers.

If $x = \alpha$ and $y = \beta$ be the least integral solution of $ax + c = by$, we shall have

$$a\alpha + c = b\beta$$

Therefore $a(bm + \alpha) + c = b(am + \beta)$,

m being any integer. Therefore, in general,

$$x = bm + \alpha$$

But we have calculated before that

$$x = q_1 y_1 + x_1 ;$$

$$\therefore q_1 y_1 + x_1 = bm + \alpha$$

Thus it is found that the minimum value α of x is equal to the remainder left on dividing its calculated value by b . whence we can calculate the minimum value of $N (=a\alpha + R_1)$. This will explain the *rationale* of the operations described in the latter portion of the rule of Āryabhaṭa I.

Bhāskara I and Kuṭṭaka Operation

In Chapter I of the *Mahābhāskarīya*, Bhāskara I has described the preliminary operation to be performed on the divisor and dividend of a pulveriser. We shall quote it from the edition of K.S. Shukla :

The divisor (which is "the number of civil days in a *yuga*") and the dividend (which is "the revolution number of the desired planet") become prime to each other on being divided by the (last non-zero) residue of the mutual division of the number of civil days in a *yuga* and the revolution number of the desired planet. The operations of the pulveriser should be performed on them (i. e. on the abraded divisor and abraded dividend). So has been said.¹

An indeterminate equation of the first degree of the type

$$\frac{ax - c}{a} = y$$

(with x and y unknown) is known in Hindu mathematics by the name of "pulveriser"—*kuṭṭakāra*). In this equation, a is called the "dividend" (*bhājya*), b the "divisor" (*bhāgahāra*), c the interpolator (*kṣepa*), x the "multiplier" (*guṇakāra*), and y the "quotient" (*labdha*).

In the pulveriser contemplated in the above stanza :

a = revolution number of a planet.

b = civil days in a *yuga*,

c = residue of the revolutions of the planet (*Śeṣa*)

1. भूदिनेष्टान्यान्योन्य भक्तशेषेण भाजि ।
हारमाज्यौदृहौ स्यातां कुट्टाकारं तयोर्विदुः ।

$x = \text{ahargāṇa}$,

and $y = \text{complete revolutions performed by the planet.}$

The text says that as a preliminary operation to the solution of this pulveriser, a and b , i.e., civil days in *yuga* and revolution-number of the planet, should be made prime to each other by dividing them out by their greatest common factor. That is to say, in solving a pulveriser, one should always make use of abraded divisor and abraded dividend.

The interpolator, i.e., the residue, should also be divided out by the same factor. (This instruction is not given in the text, but it is implied that the residue should be computed for the abraded dividend and abraded divisor).

Set down the dividend above and the divisor (*hāra*) below that. Divide them mutually and write down the quotients (*labdha*) of division one below the other (in the form of a chain). (When an even number of quotients is obtained) think out by what number the (last) remainder be multiplied so that the product being diminished by the (given) residue be exactly divisible (by the divisor corresponding to that remainder). Put down the chosen number called *mati* below the chain and then the new quotient underneath it. Then by the chosen number multiply the number which stands just above it, and to the product add the quotient (written below the chosen number). (Replace the upper number by the resulting sum and cancel the number below). Proceed afterwards also in the same way (until only two numbers remain). Divide the upper number (called the "multiplier") by the divisor by the usual process and the lower one (called the "quotient") by the dividend: the remainders (thus obtained) will respectively be the *ahargāṇa* and the revolutions etc. or what one wants to know.¹

We shall illustrate the operation by taking a problem from the *Laghu-Bhāskariya* (VIII. 17):

The sum, the difference, and the product increased by one, of the residues of the revolution of Saturn and Mars—each is a perfect square. Taking the equations

furnished by the above and applying the method of such quadratics, obtain the (simplest) solution by the substitution of 2, 3 etc. successively in the general solution). Then calculate the *ahragana* and the revolutions performed by Saturn and Mars in that time together with the number of solar years elapsed.¹

Let x and y denote the residues of the revolution of Mars and Saturn respectively. Then we have to find out two numbers x and y such that each of the expressions $x+y$, $x-y$ and $xy+1$ may be a perfect square.

Let $x+y=4P^2$ and $x-y=4Q^2$, so that

$$x=2P^2+2Q^2$$

$$y=2P^2-2Q^2$$

and therefore $xy+1=(2P^2-1)^2+4(P^2-Q^2)$

Hence the condition that $xy+1$ be a perfect square is that $P^2=Q^4$. Substituting these values, we have

$$x=2(Q^4+Q^2)$$

$$y=2(Q^4-Q^2)$$

where Q may possess any of the values 2, 3, 4,.....but not 1. (We neglect the case when x or y is zero).

—LBh. VI. 11. 17

Putting $Q=2$, we get $x=40$ and $y=24$, which is the least solution.

Assuming now that the residues of the revolution (*maṇḍa-laja-seṣa*) of Saturn and Mars are 24 and 40 respectively, we have to obtain the *ahargana* (which means the number of mean civil days elapsed since the beginning of Kaliyuga, or, in fact, any epoch).

The revolution-number of Saturn is 146564, and the number of civil days in a *yuga* is 1,577,917,500. In the present problem, these are respectively the dividend and the divisor. Their H.C.F. is 4, so that dividing them out by 4 we get 36641 and 394,479,375 as the abraded dividend and abraded divisor respectively. We have, therefore, to solve the pulveriser

$$\frac{36641x - 24}{394479375} = y$$

where x and y denote the *ahargana* and the revolutions respectively made by Saturn.

Mutually dividing 36641 and 394479375, we get

$$\begin{array}{r} 36641 \overline{) 394479375} \quad (10766 \\ \underline{394477006} \end{array}$$

$$\begin{array}{r} 2369 \overline{) 36641} \quad (15 \\ \underline{35535} \end{array}$$

$$1106 \overline{) 2369} \quad (2$$

$$\begin{array}{r} \overline{) 157} \quad (7 \\ \underline{1099} \end{array}$$

$$\begin{array}{r} \overline{) 7} \quad (2 \\ \underline{154} \end{array}$$

$$\begin{array}{r} \overline{) 3} \quad (1 \\ \underline{6} \end{array}$$

$$\begin{array}{r} 1 \times 27 - 24 = 3 \\ \underline{3} \\ 0 \end{array}$$

We have chosen here the number 27 as the optional number (*mati*). In fact, *mati* may be chosen at any stage after an even number of quotients are obtained.

Writing down the quotients one below the other as prescribed in the rule, we get the chain

10766
15
2
7
22
2
(*mati*) 27
1

Reducing the chain, we successively get

10766	10766	10766	10766	10766	10766	3108044439
						(multiplier)
15	15	15	15	15	288689	288689
						(quotient)
2	2	2	2	18665	18665	
7	7	7	8714	8714		
22	22	1237	1237			
2	55	55				
(<i>mati</i>)						
27	27					
1						

(it would be seen in this reduction of chain that *mati* or 27×2 plus 1 is 55; 55×22 plus 27 is 1237; 1237×7 plus 55 is 8714; 8714×2 plus 1237 is 18665; 18665×15 plus 8714 is 288689; and finally 288689×10766 plus 18665 is 3108044439 which is the multiplier).

Dividing 3108044439 by 394479375, and 288689 by 36641, we obtain 346688814 and 32202 respectively as remainders. (This division is performed only when the multiplier and quotient are greater than the divisor and dividend respectively). These are the minimum values of x and y satisfying the above equation.

Therefore, the required *ahargana* = 346688814 and the revolutions performed by Saturn = 32202.

To obtain the *ahargana* and the revolutions of Mars, one has to solve the equation :

$$\frac{191402z - 40}{131493125} = w$$

where z and w denote the *ahargana* and the revolutions performed by Mars respectively.

The general solution of this equation is

$$z = 131493125s + 118076020$$

$$w = 191402s + 171872$$

where $s = 0, 1, 2, 3, \dots$. When $s = 0$, we have the least solution.

Brahmagupta's Rules Concerning Indeterminate Analysis of the First Degree

For the solution of Āryabhaṭa's problem, Brahmagupta gives the following rule :

What remains when the divisor corresponding to the greater remainder is divided by the divisor corresponding to the smaller remainder—that (and the latter divisor) are mutually divided and the quotients are severally set down one below the other. The last residue (of the reciprocal division after an even number of quotients has been obtained) is multiplied by such an optional integer that the product being added with the difference of the (given) remainders will be exactly divisible (by the divisor corresponding to that residue). That optional multiplier and then the (new) quotient just obtained should be set down (underneath the listed quotients). Now, proceeding from the lower-most number (in the column), the penultimate is multiplied by the number just above it and then added by the number just below it. The final value thus obtained (by repeating the above process) is divided by the divisor corresponding to the smaller remainder. The residue being multiplied by the divisor corresponding to the greater remainder and added to the greater remainder will be the number in view.¹

1. अशिकाग्रभागाहारादूनाग्रच्छेद भाजिताच्छेषम् ।
यत् तत् परस्परहृतं लब्धमवोऽधः पृथक् स्थाप्यम् ॥
शेषं तदेष्टुगुणितं यथाऽऽयोरन्तरेण संयुक्तम् ।
शुच्यति गुणकः स्थाप्यो लब्धं चान्त्यादुपान्त्यगुणः ॥
स्वोर्ध्वोऽन्त्य युतोऽग्रान्तो हीनाग्रच्छेदभाजितः शेषम् ।
अशिकाग्रच्छेदहत मशिकाग्रमुतं मकत्यग्रम् ॥

Brahmagupta further observes :

Such is the process when the quotients (of mutual division) are even in number. But if they be odd, what has been stated before as negative should be made as positive, or as positive should be made negative.¹

Regarding the direction for dividing the divisor corresponding to the greater number by the divisor corresponding to the smaller remainder, Pṛthūdaka Svāmī (860A.D.) observes that it is not absolute, rather optional; so that the process may be conducted in the same way by starting with the division of the divisor corresponding to the smaller remainder by the divisor corresponding to the greater remainder. But in this case of inversion of the process, he continues, the difference of the remainders, must be negative.

That is to say, the equation

$$by = ax + c$$

can be solved by transforming it first to the form

$$ax = by - c$$

so that we shall have to start with the division of b by a .

For the details of the "Theory of the pulveriser" as applied to the problems in Astronomy, the reader is referred to the writings of Bhaṭṭa Govind, translated by K.S. Shukla, and given as an Appendix to the edition of the *Laghu-Bhāskariya*. For the *rationale* of the rules in relation to *kuṭṭaka* or the pulveriser operation, one may also refer to the chapters by Datta and Singh in the *History of Hindu Mathematics: Algebra*.

$$\text{Solution of } by = ax \pm 1.$$

This simple indeterminate equation has a special use in astronomical calculations and therefore, Indian algebraists have paid special attention to it. In fact, this equation is solved exactly in the same way as the equation $by = ax \pm c$; it is a parti-

1. एवं समेषु विषमेष्वृणं धनं धनमृणं यदुक्तं तत् ।

अणधनयोर्व्यस्तत्वं गुणय प्रक्षेपयोः कार्यम् ॥

—BrSpSi. XVIII. 13.

cular case only of the more general latter equation. Of course, there is a little justification also for treating it separately, since both the types of equations represent two different physical conditions of the astronomical problems. In the case of $by=ax\pm c$, the conditions are such that the value of either y or x , more particularly of the latter, has to be found and the rules for solution formulated with that objective. But in the case of the equation $by=ax\pm 1$, the physical conditions require the values of both y and x .

The equation $by=ax\pm 1$ is usually known by the name *sthira-kuṭṭaka*, literally meaning the 'constant pulveriser' Pṛthūdaka Svāmī also names it as *dyḍha-kuṭṭaka* meaning firm-pulveriser. Later on this term *dyḍha* was confined to another sense, equivalent to *nicched* (having no divisor) or *nirapavarta* (irreducible). The origin of the name *sthira-kuṭṭaka* or constant pulveriser has been explained by Pṛthūdaka Svāmī as being due to the fact that the interpolator (± 1) is here invariable.

For the solution of this equation, we shall quote Bhāskara I's rule and the rule by Brahmagupta. Bhāskara I writes in this connection as follows :

The method of the pulveriser is applied also after subtracting unity. The multiplier and quotient are respectively the numbers above and underneath. Multiplying those quantities by the desired number divide by the reduced divisor and dividend; the residues are in this case known to be the (elapsed) days and (residues of) revolutions respectively¹.

The pulveriser

$$\frac{ax-c}{b}=y \quad \dots (1)$$

may be written as

$$\frac{aX-1}{b}=Y \quad \dots (2)$$

where $x=cX$ and $y=cY$. If $X=\alpha$, $Y=\beta$ is a solution of (2), then $x=c\alpha$, $y=c\beta$ will be a solution of (i). Hence the above rule.

1. रूपमेकमपास्यापि कुदाकारः प्रसाध्यते ।
गुण्यकालेऽथ लब्धं च राशी स्यातामुपर्येषः ॥

Brahmagupta's Rule in this connection is as follows :

Solution of $by = ax - 1$:

Divide them (i.e., the abraded coefficient of the multiplier and the divisor) mutually and set down the quotients one below the other. The last residue (or the reciprocal division after an even number of quotients has been obtained) is multiplied by an optional integer such that the product being diminished by unity will be exactly divisible (by the divisor corresponding to that residue). The (optional) multiplier and then this quotient should be set down (underneath the listed quotients). Now proceeding from the lower most term to the uppermost, by the penultimate multiply the term just above it and then add the lowermost number. (The uppermost number thus calculated being divided by the reduced divisor, the residue (is the quantity required. This is the method of the constant pulveriser¹.

Solution of

$$by + ax = \pm c$$

Indian algebraists usually transformed this equation as $by = -ax + c$, so that it appeared as a particular case of $by = ax + c$, in which a was negative. Brahmagupta has been the first person to solve this equation, but the rule given by him is obscure :

The reversal of the negative and positive should be made of the multiplier and interpolator.²

Prthudaka Svāmī has tried to explain it, but he too is not very clear. He says :

1. हृतयोः परस्परं यच्छेषं गुणकार भागद्वययोः ।
तेन हतौ निश्छेदौ तावेव परस्परं हृतयोः ॥
लब्धमधोऽधः स्थाप्य तथेष्ट गुणकारसङ्गुण्यं शेषम् ।
शुद्ध्यति यथैकहीनं गुणकः स्थाप्यः फलं चात्स्यात् ॥
अग्रान्तमुपान्तयेन स्वोर्ध्वो गुणितोऽन्त्य संयुतो भक्तम् ।
निःशेषभागद्वारेणैवं स्थिरकुट्टकः शेषम् ॥

—BrSpSi. XVIII. 9-11

2. एवं समेषु विषमेष्वर्णं धनं धनमृणं यदुक्तं तत् ।
अणधनयोर्व्यस्तत्वं गुणयप्रक्षेपयोः कार्यम् ॥

BrSpSi XVIII. 13

If the multiplier be negative, it must be made positive; and the additive must be made negative : and then the method of the pulveriser should be employed.

Prthūdaka Svāmī, however, does not indicate how to derive the solution of the equation .

$$by = -ax + c \quad \dots(1)$$

from that of the equation

$$by = ax - c \quad \dots(2)$$

The method, however, seems to have been this :

Let $x=a$, $y=\beta$ be the minimum solution of (2). Then we get

$$b\beta = a^2 - c$$

$$\text{or} \quad b(a-\beta) = -a(a-b) + c$$

Hence $x=a-b$, $y=a-\beta$ is the minimum solution of (1). This rule is very clearly indicated by Bhāskara II and others.

We shall give two examples from Bhāskara II (*Bījaganita*) to illustrate the rule :

Example I.

$$13y = -60x + 3$$

By the method described before, we find that the minimum solution of

$$13y = 60x + 3$$

is $x=11$, $y=51$. Subtracting these values from their respective abraders, namely 13 and 60, we get 2 and 90. Then by the maxim : "In the case of the dividend and divisor being of different signs, the results from the operation of division should be known to be so", making the quotient negative we get the solution of

$$13y = -60x + 3$$

as $x=2$, $y=-9$. Subtracting these values again from their respective abraders (13, 60), we get the solution of

$$13y = -60x - 3$$

as $x=11$, $y=-51$.

Example II.

$$11y = 18x + 10$$

Proceeding as before, we find the minimum solution of

$$11y=18x+10$$

to be $x=8$, $y=14$. These will also be the values of x and y in the case of the negative divisor but the quotient for the reasons stated before should be made negative. So the solution of

$$-11y=18x+10$$

is $x=8$, $y=-14$. Subtracting these (i.e., their numerical values) from their respective abraders, we get the solution of

$$-11y=18x-10$$

as $x=3$, $y=-4$,

“When the divisor is positive or negative the numerical values of the quotient and multiplier remain the same : when either the divisor or the dividend is negative, the quotient must always be known to be negative”¹.

One Linear Equation in More Than Two Unknowns

Whenever a linear equation involves more than two unknown's the Indian algebraists used to assume arbitrary values for all the unknowns except two and then to apply the method of *kut-taka* or “pulveriser”. In this connection, Brahmagupta says :

The method of the pulveriser (should be employed if there be present many unknowns (in any equation)²,

1. Bhāskara II gives the following rule :

“Those (the multiplier and quotient) obtained for a positive dividend being treated in the same manner give the results corresponding to a negative dividend.”

The treatment alluded to in this rule is that of subtraction from the respective abraders. He has further elaborated it thus :

The multiplier and quotient should be determined by taking the dividend, divisor and interpolator as positive. They will be the quantities for the additive interpolator. Subtracting them from their respective abraders, the quantities for a negative interpolator are found. If the dividend or divisor, be negative, the quotient should be stated as negative, the quotient should be stated as negative.

—*Bījaganita*

1. आद्याद्वर्णादन्यान् वर्णान् प्रोक्ष्याद्यमानमाद्यहृतम् ।
सदृशच्छेदाक्सङ्खद् द्वौ व्यस्तौ कुर्वो बहुषु ॥

—*BrSpSi. XVIII. 51*

We shall take up one of the problems posed by Brahmagupta concerning astronomy and leading to the equation :¹

$$197x - 1644y - z = 6302.$$

Hence

$$x = \frac{1644y + z + 6302}{197}$$

The commentator assumes $z=131$. Then

$$x = \frac{1644y + 6433}{197};$$

hence by the usual method of the pulveriser

$$x=41; y=1.$$

General Problem of Remainders

A certain type of simultaneous indeterminate equations of the first degree arise out of the general problem of remainders which may thus be stated : To find a number N which being severally divided by $a_1, a_2, a_3, \dots, a_n$, leaves as remainders $r_1, r_2, r_3, \dots, r_n$ respectively.

While dealing with such a case, we shall have the following series of equations :

$$N = a_1x_1 + r_1 = a_2x_2 + r_2 = a_3x_3 + r_3 = \dots = a_nx_n + r.$$

We have reasons to believe that the method of solution of these equations was known to Āryabhaṭa I. In the translation of the verse in the *Āryabhaṭīya*, II. 32-33 (the translation of which we have already given), the term *dvicchedāgram* should be translated as "the result will be the remainder corresponding to the product of the two divisors", instead of "the result will be the number corresponding to the two divisors." (the last line of the translation). This explanation is in fact given by Bhāskara I, the direct disciple and earliest commentator of Āryabhaṭa I. Such a rule is clearly stated by Brahmagupta².

1. अंशकरोषेय युतात् लिप्ताशेषात्तदन्तरादथवा ।

मानोर्द्विने कुण्ठं यः कथयति कुट्टकः सः ॥

—*BrSpSi*. XVIII. 55

2. स्वोर्ध्वोऽन्त्ययुतोऽग्रान्तो ह्रीनाम्यच्छेदभाजितः शेषम् ।

अधिकम्यच्छेदह्यतमधिकम्ययुतं भवत्ययम् ॥

—*BrSpSi*. XVIII. 5

The rationale of this method is not difficult. I shall quote it from the book of Datta and Singh: Starting with the consideration of the first two divisors, we have

$$N = a_1x_1 + r_1 = a_2x_2 + r_2.$$

By the method described before, we can find the minimum value α of x_1 satisfying this equation. Then the minimum value of N will be $a_1\alpha + r_1$. Hence the general value of N will be given by

$$\begin{aligned} N &= a_1 (a_2t + \alpha) + r_1 \\ &= a_1a_2t + a_1\alpha + r_1 \end{aligned}$$

where t is an integer. Thus $a_1\alpha + r_1$ is the remainder left on dividing N by a_1a_2 as stated by Āryabhaṭa I and Brahmagupta. Now taking into consideration the third condition, we have

$$N = a_1a_2t + a_1\alpha + r_1 = a_3x_3 + r_3$$

which can be solved in the same way as before. Proceeding in this way successively, we shall ultimately arrive at a value of N satisfying all the conditions ;

Prthūdaka Svāmī remarks :

Wherever the reduction of two divisors by a common measure is possible, there 'the product of the divisors' should be understood as equivalent to the product of the divisor corresponding to the greater remainder and quotient of the divisor corresponding to the smaller remainder as reduced (i.e. divided) by the common measure.¹ When one divisor is exactly divisible by the other, then the greater remainder is the (required) remainder and the divisor corresponding to the greater remainder is taken as 'the product of the divisors'. (The truth of) this may be investigated by an intelligent mathematician by taking several symbols.

As an illustration we shall take up a problem quoted by Bhāskara II in his *Bijaganita*, and which in its solution follows the method of Āryabhaṭa I. Prthūdaka Svāmī while commenting on several verses from Brahmagupta (*BrSpSi*. XVIII. 3-6)

-
1. i.e., if p be the L.C.M. of a_1 and a_2 , the general value of N satisfying the above two conditions will be

$$N = pt + a_1\alpha + r_1,$$

instead of

$$N = a_1a_2t + a_1\alpha + r_1.$$

observes that such problems were very popular amongst the ancient Indian mathematicians.

Problem : To find a number N which leaves remainders 5, 4, 3, 2 when divided by 6, 5, 4, 3 respectively.

That is to solve the equations :

$$N=6x+5=5y+4=4z+3=3w+2.$$

We have since $N=6x+5=5y+4$,

$$x = \frac{5y-1}{6}$$

But x must be integral, so $y=6t+5$, $x=5t+4$

$$\text{Hence } N=30t+29$$

Again $N=30t+29=4z+3$

$$\text{Therefore, } t = \frac{2z-13}{15}$$

Since t must be integral, we must have $z=15s+14$;
hence $t=2s+1$. Therefore

$$N=60s+59.$$

The last condition is identically satisfied. The method given here is the one followed by *Prthudaka Svāmī*.

Thus when $N=60s+59=6x+5$

$$x = \frac{60s+54}{6} = 10s+9 \quad \dots(1)$$

Again, when $N=60s+59=5y+4$,

$$y = \frac{60s+55}{5} = 12s+11$$

Again when $N=60s+59=4z+3$

$$z = \frac{60s+56}{4} = 15s+14$$

Lastly, when $N=60s+59=3w+2$,

$$w = \frac{60s+57}{3} = 20s+19.$$

Varga Prakṛti or Kṛti Prakṛti or Square-Nature

The word *varga-prakṛti* (literally meaning 'square-nature') has been given by Indian algebraists to the indeterminate quadratic equation

$$Nx^2 \pm c = y^2$$

Here in this equation the absolute number c should be *rūpa* (or unity), which means the equation

$$Nx^2 \pm 1 = y^2$$

or it may be any absolute number. The most fundamental equation of this class has been regarded as

$$Nx^2 + 1 = y^2$$

where N is a non-square integer.

This branch of mathematics has originated from the number which is the *prakṛti* of the square of *yāvat*, etc. (the unknown x etc.), and therefore, it is called *varga-prakṛti*. The quantity N of the above equation is known as *Prakṛti*. Brahmagupta uses the term *GUṆAKA* (*multiplier*) for the same purpose¹.

This term *guṇaka* together with its variation *guṇa* appears occasionally also in the writings of later authors. For example, Śrīpati (*Siddhānta-sekhara*. XIV. 32) employs the term *guṇaka* where as Bhāskara II and Nārāyaṇa use the term *guṇa* in their *Bījagaṇitas*.

In this connection, we would now like to quote from Pṛthūdaka Svāmī (863 A.D.) from his commentary on the *Brahmasphuṭasiddhānta* :

Here are stated for ordinary use the terms which are well known to people. The number whose square, multiplied by an optional multiplier and then increased or decreased by another optional number, becomes capable of yielding a square-root, is designated by the term the "lesser root" *kaniṣṭha pada* or the "first root" *ādya-mūla*). The root which results, after those operations have been performed is called by the name the "greater root" (*jyeṣṭha pada*) or the "second root" (*anya-mūla*). If there be a number multiplying both these roots, it is called the "augmenter" (*udvartaka*); and on the contrary, if there be a number dividing the roots, it is called the "abridger" (*apavartaka*).

Thus in the equation

$$Nx^2 \pm c = y^2,$$

1. मूलं द्विवेष्ट कर्माद् गुणक गुणादिष्वयुक्त विद्मलान्च ।

आववधो गुणकगुणः सहान्यधातेन कृतमन्त्यम् ॥

2. BrSpSi. XVIII. 64 (Com.)

x is known as the lesser root, y is the greater root, N is the multiplier (*gunaka*) and c is interpolator or *kṣepaka*. Bhāskara II has used the word "*hrasvamūla*" for *kaniṣṭha pada* or *ādyamūla* literally meaning "lesser root". The earlier terms, the "first root" (*ādyamūla*) for the value of x and the "second root" or the "last root" *antya-mūla* for the value of y are quite free from ambiguity. Their use is found in the algebra of Brahmagupta. The later terms appears in the works of his commentator Pṛthūdaka Svāmī.

Brahmagupta uses the term *kṣepa*, *prakṣepa* or *prakṣepaka* in the sense of "interpolator." Again, when negative, the interpolator is sometimes distinguished as the "subtractive" or *sodhaka* and the positive interpolator is then called "the additive."

Lemmas of Brahmagupta

Prior to our giving the general solution of the Square-nature or *Varga-Prakṛti*, it would be better to give two Lemmas established by Brahmagupta. We have the following in the *Brahmasphuṭasiddhānta* :

Of the square of the optional number multiplied by the *gunaka* and increased or decreased by an other optional number, *iṣṭa*, (extract) the square root. (Proceed) twice. The product of the first roots multiplied by the *gunaka* together with the product of the second roots will give a (fresh) second root; the sum of their cross-products will be a (fresh) first root. The (corresponding) interpolator will be equal to the product of the (previous) interpolators.¹

There is a little difficulty in ascertaining the real sense of the rule given in these lines since the word *dvidha* (twice) has two implications. Firstly, it may mean that the earlier operations of finding roots are made on two optional numbers with two optional interpolators, and with the results thus obtained the subse-

1. मूलं द्विवेष्टकानां गुणकं गुणादिष्टयुतं विहीनाच्च ।

आवधयो गुणकगुणः सहान्त्यवातेन कृतमन्त्यम् ॥

वज्रवैज्यं प्रथमं प्रश्ने पः क्षेपवध तुल्यः ।

प्रश्ने पशोषकहते मूले प्रश्ने पके रूपे ॥

quent operations of their composition are performed. Secondly, it may also mean that the earlier operations are made with one optionally chosen number and one interpolator, and the subsequent ones are carried out after the repeated statement of those roots for the second time. It is also implied that in the composition of the quadratic roots, their products may be added together or subtracted from each other.

In other words, if $x=a, y=\beta$ be a solution of the equation :

$$Nx^2+k=y^2,$$

and $x=a', y=\beta'$ be a solution of

$$Nx^2+k'=y'^2,$$

then according to the above

$$x=\alpha\beta'\pm\alpha'\beta, y=\beta\beta'\pm Na\alpha'$$

is a solution of the equation

$$Nx^2+kk'=y'^2.$$

In other words, if

$$Na^2+k=\beta^2$$

$$Na'^2+k'=\beta'^2$$

then

$$N(\alpha\beta'\pm\alpha'\beta)^2+kk'=(\beta\beta'\pm Na\alpha')^2 \quad (I)$$

In particular, taking $a=a', \beta=\beta'$ and $k=k'$, Brahmagupta finds from a solution $x=a, y=\beta$ of the equation

$$Nx^2+k^2=y^2$$

a solution $x=2a\beta, y=\beta^2+Na^2$ of the equation

$$Nx^2+k=y^2$$

That is, if

$$Na^2+k=\beta^2$$

then

$$N(2a\beta)^2+k^2=(\beta^2+Na^2)^2 \quad (II)$$

This result will be hereafter called *Brahmagupta's Corollary*.

Thus *Brahmagupta's First Lemma* says that if two solutions of the equation (of the Square-nature) $Nx^2+1=y^2$ are known, then any number of other solutions can be found. For example if two solutions of the Square-nature are (a, b) and also (a', b') , then two other solutions will be :

$$x=ab'+a'b, y=bb'\pm Na a'.$$

We can compose this solution with the previous ones, and get another solution, and thus proceed on to innumerable solutions. From *Brahmagupta's Corollary to First Lemma* we get another set of solutions. If (a, b) be solution of the Square-nature, then another solution of it is

$$x=2ab, \text{ and } y=b^2+Na^2$$

Thus even if we have only one solution, we can get the other solution also (since N is known), and thus we can get any number of solutions one after the other by this Principle of Composition.

Brahmagupta's Lemmas have been described by Bhāskara II (1150 A.D.) in the following words :

Set down successively the lesser root (*hrasva*), greater root (*jyeṣṭha*) and interpolator (*kṣepaka*); and below them should be set down in order the same or another (set of similar quantities). From them by the Principle of Composition (*Bhāvanā*) can be obtained numerous roots. Therefore the Principle of Composition will be explained here. (Find) the two cross-products (*vajrābhyāsa*) of the two lesser and the two greater roots; their sum is a lesser root. Add the product of the two lesser roots multiplied by the *prakṛti* to the product of the two greater roots, the sum will be a greater root. In that (equation) the interpolator will be the product of the two previous interpolators. Again the difference of the two cross-products is a lesser root. Subtract the product of the two lesser roots multiplied by the *prakṛti* from the product of the two greater roots; (the difference) will be greater root. Here also the interpolator is the product of the two (previous) interpolators.¹

1. ह्रस्वज्येष्ठ द्वे पदान् न्यस्य तेषां तानन्यान् वाऽथो निवेश्य क्रमेण ।

Bhāskara II, *Bijaganita*, *VargaPrakṛti*. 2-4

Principle of Composition

The above results have been technically known amongst Indian algebraists as *Bhāvanā* (demonstrated or proved, hence theorem or lemma). The word *bhāvanā* also means "composition or combination" in algebra. *Bhāvanā* may be of two types: *Samāsa Bhāvanā* (or addition Lemma, or additive composition) and *Antara Bhāvanā* (or subtraction Lemma or subtractive composition). Whenever, again, the *bhāvanā* is made with two equal sets of roots and interpolators, it is technically named as *Tulya Bhāvanā* (or composition of equals), and when with two unequal sets of values then it is known as *Atulya Bhāvanā* (or composition of unequals).

Proof of Brahmagupta's Lemmas

It is significant to be indicated that Brahmagupta's Lemmas were rediscovered by Euler in 1764 and by Lagrange in 1768, and a considerable importance was attached to them. Kṛṣṇa, (1580 A.D.) the commentator on the *Bījaganita* of Bhāskara II gives the following proof of Brahmagupta's Lemmas:

Let (α, β) and (α', β') be the two solutions of the equation

$$nx^2 + k = y^2.$$

we have

$$N\alpha^2 + k = \beta^2$$

$$N\alpha'^2 + k = \beta'^2$$

Multiplying the first equation by β'^2 , we get

$$N\alpha^2\beta'^2 + k\beta'^2 = \beta^2\beta'^2$$

Now, substituting the value of factor β'^2 of the interpolator from the second equation, we get

$$N\alpha^2\beta'^2 + k(N\alpha'^2 + k') = \beta^2\beta'^2$$

$$\text{or } N(\alpha^2\beta'^2 + Nk\alpha'^2 + kk') = \beta^2\beta'^2$$

Again, substituting the value of k from the first equation in the second term of the left-hand side expression, we have

$$N\alpha^2\beta'^2 + N\alpha'^2(\beta^2 - N\alpha^2) + kk' = \beta^2\beta'^2$$

$$\text{or } N(\alpha^2\beta'^2 + \alpha'^2\beta^2) + kk' = \beta^2\beta'^2 + N^2\alpha^2\alpha'^2$$

Adding $\pm 2N\alpha\beta\alpha'\beta'$ to both sides, we get

$$N(\alpha\beta' \pm \alpha'\beta)^2 + kk' = (\beta\beta' \pm N\alpha\alpha')^2$$

Brahmagupta's Corollary also follows at once from the above by putting $\alpha'=\alpha$, $\beta'=\beta$ and $k'=k$.

$$N(2\alpha\beta)^2 + k^2 = (\beta^2 \pm N\alpha^2)^2$$

Thus the roots are $x=2\alpha\beta$ and $y=\beta^2 \pm N\alpha^2$ which is the Corollary.

It would be seen that modern historians of mathematics are incorrect when they say that Fermat (1657) was the first to state that the equation $Nx^2+1=y^2$, where N is a non-square integer has an unlimited number of solutions in integers. For this assertion, history takes us to the early Seventh Century A.D. when Brahmagupta wrote his classical treatise, the *Brāhmasphuṭasiddhānta*, and gave the well known two Lemmas and the Corollary to the first Lemma.

Second Lemma of Brahmagupta

In the *Brāhmasphuṭa siddhānta*, we find another important Lemma by Brahmagupta stated as follows :

On dividing the two roots (of a square Nature) by the square-root of its additive or subtractive, the roots for interpolator unity (will be found).¹

This Lemma when expressed in the modern language of algebra would mean that if $x=\alpha, y=\beta$ be a solution of the equation.

$$Nx^2 + k^2 = y^2$$

then $x=\alpha/k, y=\beta/k$ is a solution of the equation

$$Nx^2 + 1 = y^2.$$

This rule, at another place, has been re-enunciated as follows :

If the interpolator is that divided by a square then the roots will be those multiplied by its square-root.²

1. प्रक्षेपशेषक इवे मूले प्रक्षेपके रूपे ।

—BrSpSi. XVIII. 65

2. कश्चिन्ने च पे तत्पदगुणिते तदा मूले ।

—BrSpSi. XVIII. 70

This rule may be expressed in terms of symbols as follows.
Suppose the *Varga-prakṛti* (Square-nature) to be

$$Nx^2 \pm p^2 d = y^2,$$

so that its interpolator (*kṣepa*) $p^2 d$ is exactly divisible by the square p^2 . Then, putting therein $u = x/p$, $v = y/p$, we derive the equation

$$Nu^2 \pm d = v^2$$

whose interpolator is equal to that of the original Square-nature divided by p^2 . It is clear that the roots of the original equation are p times those of the derived equation.

Rational Solution

Indian algebraists have usually suggested the following method to obtain a first solution of $Nx^2 + 1 = y^2$:

Take an arbitrary small rational number, α , such that its square multiplied by the *gunaka* N and increased or diminished by a suitably chosen rational number k will be an exact square.

In other words, we shall have to obtain empirically a relation of the form

$$N\alpha^2 \pm k = \beta^2$$

where α , k , and β are rational numbers. Let us call this relation as the *Auxiliary Equation*. Then by Brahmagupta's Corollary, we get from it the relation

$$N(2\alpha\beta)^2 + k^2 = (\beta^2 + N\alpha^2)^2,$$

or
$$N\left(\frac{2\alpha\beta}{k}\right)^2 + 1 = \left(\frac{\beta^2 + N\alpha^2}{k}\right)^2$$

Hence, one rational solution of the equation $Nx^2 + 1 = y^2$ is given by

$$x = \frac{2\alpha\beta}{k}, \quad y = \frac{\beta^2 + N\alpha^2}{k}$$

Work on the rational solution of the Square-nature has been also done by Śrīpati. In fact, his solution, given in 1039 A.D. is of historical significance. He derives the rational solution without the aid of the "auxiliary equation." He gives the following rule :

Unity is the lesser root. Its square multiplied by the *prakṛti* is increased or decreased by the *prakṛti* combined with an (optional) number whose square-root will be the greater root. From them will be obtained two roots by the Principle of Composition¹

Thus if m^2 be the rational number optionally chosen, one shall have the identity :

$$N.1^2 + (m^2 - N) = m^2,$$

or
$$N.1^2 - (N - m^2) = m^2$$

Then by applying Brahmagupta's Corollary we get

$$N(2m)^2 + (m^2 \vee N)^2 = (m^2 + N)^2$$

$$\therefore N \left(\frac{2m}{m^2 \vee N} \right) + 1 = \left(\frac{m^2 + N}{m^2 \vee N} \right)^2$$

Hence

$$x = \frac{2m}{m \vee N} \quad y = \frac{m^2 + N}{m^2 \vee N}$$

where m is any rational number, is a solution of the equation $Nx^2 + 1 = y^2$.

This rational solution of the *varga-prakṛti* which was used by Śrīpati in 1039 A.D. was rediscovered in Europe by Brouncker in 1657.

We shall close this discussion by taking an illustration from Bhāskara II :

Problem : Tell me, O mathematician, what is that square which multiplied by 8 becomes, together with unity, a square; and what square multiplied by 11 and increased by unity, becomes a square.

This means that we have to solve the equations :

$$8x^2 + 1 = y^2 \quad \dots\dots(i)$$

$$11x^2 + 1 = y^2 \quad \dots\dots(ii)$$

In the second example, let us assume 1 as the lesser root. Following the method of Śrīpati, let us multiply its square by the *prakṛti* (here in eq. ii, *prakṛti* is 11), then let us subtract 2 (an optional number) and then extracting the square-roots we

get the greater root as 3. Hence the statement for the composition is

$$\begin{array}{llll} m=11 & l=1 & g=3 & i=-2 \\ & l=1 & g=3 & i=-2 \end{array}$$

Here m =multiplier (*gunaka* or *prakṛti*), l =lesser root (*kaniṣṭha-mūla*), g =greater root (*jyeṣṭha-mūla*) and i =interpolator (*kṣepa*).

Here we have set down successively the lesser root, greater root and interpolator, and below them again set down the same (See Brahmagupta's Lemmas described by Bhāskara II). Now proceeding as before we obtain the roots for the additive 4 :

$$l=6, g=20, \text{ (for) } i=4.$$

Then by the rule :

"If the interpolator (of a *varga-prakṛti* or Square-nature) divided by the square of an optional number be the interpolator (of another Square-nature), then the two roots (of the former) divided by that optional number will be the roots (of the other). Or, if the interpolator be multiplied, their roots should be multiplied."¹

are found the roots for the additive unity

$$l=3, g=10 \text{ (for) } i=1.$$

Whence by the Principle of Composition of Equals, we get the lesser and greater roots : $l=60, g=199$ (for) $i=1$. In this way an infinite number of roots can be deduced.

Alternative method:-Bhāskara II has given another method for finding the two roots for the additive unity :

Or divide twice an optional number by the difference between the square of that optional number and the *prakṛti*. This (quotient) will be the lesser root (of a Square-nature) when unity is the additive. From that (follows) the greater root.²

-
1. इष्टवर्गहतः क्षेपः क्षेपः स्यादिष्टभाजिते ।
मूले ते स्तोऽथवा क्षेपः क्षुरणः क्षुरणो तदा पदे ॥

Bijaganita II. 5.

2. *Siddhānta-śekhara*, XIV. 32.

Let us solve the first example $8x^2+1=y^2$. We assume the optional number to be 3. Its square is 9; the *prakṛti* of multiplier is 8, their difference is $9-8=1$. Dividing by this twice the optional number (2×3 , i.e. 6), namely 6, we get the lesser root for the additive unity as 6. Whence proceeding as before, we get the greater to be 17. Thus here $x=6$ and $y=17$.

Let us use this method for the equation $11x^2+1=y^2$. Let the optional number be 3. Its square is 9; multiplier or *prakṛti* is 11; the difference is $11-9=2$; dividing by this twice the optional number (2×3), namely 6, we get $6/2=3$, which is the lesser root. Consequently the greater root would be 10. Thus for this equation $x=3$ and $y=10$.

Solution in Positive Integers

The Indian algebraists usually aimed at obtaining solutions of the *varga-prakṛti* or Square-nature in positive integers or *abhinna*. The tentative methods of Brahmagupta and Śrīpati always did not furnish solutions in positive integers. These authors, however, discovered that if the interpolator of auxiliary equation in the tentative method be ± 1 , ± 2 or ± 4 , an integral solution of the equation $Nx^2+1=y^2$ can always be found. Thus Śrīpati says :

If 1, 2 or 4 be the additive or subtractive (of the auxiliary equation), the lesser and greater roots will be integral (*abhinna*)¹.

(i) If $k = \pm 1$, then the auxiliary equation will be

$$N\alpha^2 \pm 1 = \beta^2$$

where α and β are integers. Then by Brahmagupta' Corollary we get

$$x = 2\alpha\beta \text{ and } y = \beta^2 + N\alpha^2$$

as the required first solution in positive integers of the equation $Nx^2+1=y^2$

1. इष्टवर्गं प्रकृत्योर्यदिर्वरं तेन वा भजेत् ।

द्विजमिष्टं कनिष्ठं तत् पदं स्यादेक संयुतौ ।

ततो ज्येष्ठमिष्टान्नयं भावनाभिस्तथेष्टतः ॥

(ii) Let $k=\pm 2$; then the auxiliary equation is

$$N\alpha^2 \pm 2 = \beta^2$$

By Brahmagupta's Corollary, we have

$$N(2\alpha\beta)^2 + 4 = (\beta^2 + N\alpha^2)^2$$

$$\text{or } N(\alpha\beta)^2 + 1 = \left(\frac{\beta^2 + N\alpha^2}{2} \right)^2$$

Hence the required first solution is

$$x = \alpha\beta, y = \frac{1}{2}(\beta^2 + N\alpha^2)$$

$$\text{Since } N\alpha^2 = \beta^2 \mp 2,$$

we have $\frac{1}{2}(\beta^2 + N\alpha^2) = \beta^2 \mp 1 = a$ whole number.

(iii) Now suppose $k = +4$: so that

$$N\alpha^2 + 4 = \beta^2$$

With an auxiliary equation like this, the first integral solution of the equation $Nx^2 + 1 = y^2$ is

$$x = \frac{1}{2}\alpha\beta$$

$$y = \frac{1}{2}(\beta^2 - 2);$$

if α is even; or

$$x = \frac{1}{2}\alpha(\beta^2 - 1)$$

$$y = \frac{1}{2}\beta(\beta^2 - 2);$$

if β is odd.

Thus we find Brahmagupta saying:

In the case of 4 as additive the square of the second root diminished by 3, then halved and multiplied by the second root will be the (required) second root: the square of the second root diminished by unity and then divided by 2 and multiplied by the first root will be the (required) first root (for the additive unity).¹

Datta and Singh has given the following *rationale* of this solution.

$$\text{Since } N\alpha^2 + 4 = \beta^2 \quad (i)$$

$$\text{we have } N(\alpha/2)^2 + 1 = (\beta/2)^2, \quad (ii)$$

Then by Brahmagupta's Corollary, we get

$$N(\alpha\beta/2)^2 + 1 = \left(\frac{\beta^2}{4} + N\frac{\alpha^2}{4} \right)^2$$

1. चतुरधिकेऽन्यपदकृतिस्त्र्यनादलिताऽन्यपद गुण्याऽन्यपदम् ॥

अन्यपद कृतिव्येकादि हताऽऽपधदहताऽऽपधदम् ॥

Substituting the value of N in the right-hand side expression from (i), we have

$$N \cdot \left(\frac{\alpha\beta}{2} \right)^2 + 1 = \left(\frac{\beta^2 - 2}{2} \right)^2 \quad (\text{iii})$$

Composing (ii) and (iii),

$$N \left\{ \frac{\alpha}{2} (\beta^2 - 1) \right\}^2 + 1 = \left\{ \frac{\beta}{2} (\beta^2 - 3) \right\}^2$$

Hence $x = \frac{1}{2} \alpha\beta$, $y = \frac{1}{2} (\beta^2 - 2)$;

and $x = \frac{1}{2} \alpha(\beta^2 - 1)$, $y = \frac{1}{2} \beta(\beta^2 - 3)$;

are solutions of $Nx^2 + 1 = y^2$.

If β be even, the first values of (x, y) are integral. If β be odd, the second values are integral.

(iv) Finally, suppose $k = -4$; the auxiliary equation is

$$Na^2 - 4 = \beta^2$$

Then the required first solution in positive integers of

$$Nx^2 + 1 = y^2 \text{ is}$$

$$x = \frac{1}{2} \alpha\beta(\beta^2 + 3) (\beta^2 + 1)$$

$$y = (\beta^2 + 2) \left\{ \frac{1}{2} (\beta^2 + 3) (\beta^2 + 1) - 1 \right\}.$$

Brahmagupta says:

In the case of 4 as subtractive, the square of the second is increased by three and by unity; half the product of these sums and that as diminished by unity (are obtained). The latter multiplied by the first sum less unity is the (required) second root; the former multiplied by the product of the (old) roots will be the first root corresponding to the (new) second root.¹

The rationale of this solution, as given by Datta and Singh is as follows:

$$Na^2 - 4 = \beta^2 \quad (\text{i})$$

$$N(a/2)^2 - 1 = (\beta/2)^2$$

Hence by Brahmagupta's Corollary, we get

$$N \left(\frac{\alpha\beta}{2} \right)^2 + 1 = \left(\frac{\beta^2}{4} + N \frac{\alpha^2}{4} \right)^2$$

1. चतुरस्रेऽन्त्यपद कृती त्रैकयुते वधदलं पृथग्व्येकम् ।

त्रैकाबाहृतमन्त्रं पदवध गुणमाद्यमान्त्यपदम् ॥

$$=\{\frac{1}{2}(\beta^2+2)\}^2 \quad (\text{ii})$$

Again applying the Corollary, we get

$$N \{\frac{1}{2}\alpha\beta(\beta^2+2)\}^2+1=\{\frac{1}{2}(\beta^4+4\beta^2+2)\}^2 \quad (\text{iii})$$

Now by the Lemma we obtain from (ii) and (iii)

$$\begin{aligned} N \{\frac{1}{2}\alpha\beta(\beta^2+3) (\beta^2+1)\}^2+1 \\ =[(\beta^2+2)\{\frac{1}{2}(\beta^2+3) (\beta^2+1)-1\}]^2 \end{aligned}$$

Hence $x=\frac{1}{2}\alpha\beta(\beta^2+3) (\beta^2+1)$,

$$y=(\beta^2+2) \{\frac{1}{2}(\beta^2+3) (\beta^2+1)-1\}$$

is a solution of $Nx^2+1=y^2$

This can be proved without difficulty that these values of x and y are integral. Since if β is even, β^2+2 is also even. And hence the above values of x and y are integral. On the other hand, if β is odd, β^2 is also odd; under these conditions β^2+1 and β^2+3 are even. In this also, therefore, the above values must be integral.

Putting $p=\alpha\beta$, $q=\beta^2+2$, we can write the above solution in the form

$$x=\frac{1}{2}p(q^2-1).$$

$$y=\frac{1}{2}q(q^2-3).$$

This was the form in which the solution was found by Euler.

Cakravāla or Cyclic Method

We have shown in the preceding articles that the most fundamental step in Brahmagupta's method for the general solution in positive integers of the equation

$$Nx^2+1=y^2$$

where N is a non-square integer, is to form an auxiliary equation of the kind

$$Na^2+k=b^2$$

where a and b are positive integers and $k=\pm 1, \pm 2$ or ± 4 . From this auxiliary equation, by the Principle of Composition, applied repeatedly whenever necessary, one can derive, as we have already shown above, one positive integral solution of the original *Varga-prakṛti* or Square-Nature. And thence again, by means of the same principle, an infinite number of other solutions in integers can be obtained. How to form an auxiliary equation of

this type was a problem, write Datta and Singh, which could not be solved completely nor satisfactorily by Brahmagupta. In fact, Brahmagupta had to depend on trial. Success in this direction was, however, remarkably attained by Bhāskara II. He evolved a simple and elegant method which assisted in deriving an auxiliary equation having the required interpolator $\pm 1, \pm 2$, or ± 4 , simultaneously with its two integral roots, from another auxiliary equation empirically formed with any simple integral value of the interpolator, positive or negative. This method has been technically known as *Cakravāla* or the *cyclic method*. This is so called because it proceeds as in a circle, the same set of operations being applied again and again in a continuous round. For the details of this method, our reader is requested to consult the Algebra of Bhāskara II and the narrative on this method as given by Datta and Singh under the title "Cyclic Method" in their *History of Hindu Mathematics: Algebra*, 1962 Edition, pp. 161-72.

Solution of Indeterminate Quadratic Equation

It is remarkable to see that Brahmagupta was the first algebraist in the history of mathematics to find a general solution of the indeterminate quadratic equation

$$Nx^2 \pm c = y^2$$

in positive integers. We have the following verse in the *Brahmasphuṭasiddhānta* in this connection:

From two roots (of a Square-nature or *varga-prakṛti*) with any given additive or subtractive, by making (combination) with the roots for the additive unity other first and second roots (of the equation having) the given additive or subtractive (can be found).¹

Let us take the following two equations:

$$a_1k = an + b; \text{ and } b_1k = bn + Na$$

From them we get : by eliminating n

$$a_1b - ab_1 = 1$$

1. रूप प्रद्वे षपदे पृथगिष्ट्वे व्यशोध्यमूलान्वात् ।

कृतवत्तद्व्यपदे वे प्रद्वे वेतेने

Hence $b_1 = \frac{a_1 b - 1}{a} =$ a whole number.

$$\begin{aligned} \text{Now } n^2 - N &= \frac{(a_1 k - b)^2 - N a^2}{a^2} \\ &= \frac{a_1^2 k^2 - 2 b k a_1 + k}{a^2} \\ &= \frac{k(a_1^2 k - 2 b a_1 + 1)}{a^2} \end{aligned}$$

Therefore $\frac{k}{a^2}(a_1^2 k - 2 b a_1 + 1)$ is a whole number.

Since a, k have no common factor, it follows that

$$\frac{a_1^2 k - 2 b a_1 + 1}{a^2} = \frac{n^2 - N}{k} = k_1 = \text{an integer.}$$

$$\begin{aligned} \text{Also } k_1 &= \frac{n^2 - N}{k} = \frac{a_1^2 k - 2 b a_1 + 1}{a^2} \\ &= \frac{a_1^2 (b^2 - N a^2) - 2 b a_1 + 1}{a^2} \\ &= \left(\frac{a_1 b - 1}{a} \right)^2 - N a_1. \end{aligned}$$

Thus having known a single solution in positive integers of the equation $Nx^2 \pm c = y^2$, says, Brahmagupta, an infinite number of other integral solutions can be obtained by making use of the integral solutions of $Nx^2 + 1 = y^2$. If (p, q) be a solution of the former equation found empirically and if (α, β) be an integral solution of the latter, then by the principle of Composition

$$x = p\beta \pm q\alpha; y = q\beta \pm Np\alpha$$

will be a solution of the former. Repeating the operations, we can easily deduce as many solutions as we like.

$$\text{FORM } Mn^2x^2 \pm c = y^2:$$

In this connection, Brahmagupta says :

If the remainder is that divided by a square, the first root is that divided by its root¹.

This seems to mean that if we have the equation

$$Mn^2x^2 \pm c = y^2 \tag{i}$$

such that the multiplier (i.e. the coefficient of x^2) is divisible

1. कर्वाच्छिन्ने गुणके प्रथमं तन्मूलं भाजितं भवति ।

by n^2 , then we are justified in saying that if we put $nx=u$, the equation (i) becomes $Mu^2 \pm c = y^2$ (ii), and clearly the first root of (i) is equal to the first root of (ii) divided by n . The corresponding second root will be the same for both the equations.

$$\text{FORM } a^2x^2 \pm c = y^2 :$$

We find Brahmagupta giving the following rule in this connection: This is a solution of a particular form of a *varga-prakṛti* or Square-nature.

If the multiplier be a square, the interpolator divided by an optional number and then increased and decreased by it, is halved. The former (of these results) is the second root; and the other divided by the square-root of the multiplier is the first root.¹

Thus the solutions of the equation

$$a^2x^2 \pm c = y^2$$

are :

$$x = \frac{1}{2a} \left(\frac{\pm c}{m} - m \right)$$

$$y = \frac{1}{2} \left(\frac{\pm c}{m} + m \right)$$

where m is an arbitrary number.

Bhāskara II and Nārāyaṇa have also given the same solutions as proposed by Brahmagupta.

Rational Geometrical Figures

In the days of the *Taittiriya Samhitā* and the *Śatapatha Brāhmaṇa*, Indian mathematicians got familiarity with the solution of such equations

$$x^2 + y^2 = z^2$$

and the results were arrived geometrically on the basis of the law of rectangle as propounded by Baudhāyana in the *Śulba Sūtras* and which goes by his name. The reader is referred to the Chapter on Baudhāyana, the first Geometer in the author's "*Founders of Sciences in Ancient India*". Baudhāyana (c. 800 B.C.) gave a

1. कौ गुणके च पः केन चिद्वृत्त्युत्तानितो दलितः ।

प्रथमोऽन्यत्रूलमन्त्रो गुणकारपदोद्भूतः प्रथमः ॥

method of transforming a rectangle into a square, which is equivalent to the algebraic identity :

$$mn = \left(m - \frac{m-n}{2}\right) - \left(\frac{m-n}{2}\right).$$

where m, n , are any two arbitrary numbers.

Brahmagupta in connection with the solution of rational triangles says :

The square of the optional (*iṣṭa*) side is divided and then diminished by an optional number; half the result is the upright, and that increased by the optional number gives the hypotenuse of a rectangle.

We shall put these statements of Brahmagupta in the algebraic language thus : If m, n be any two rational numbers, then the sides of a right-angled triangle will be

$$m, \frac{1}{2} \left(\frac{m^2}{n} - n \right), \frac{1}{2} \left(\frac{m^2}{n} + n \right)$$

This Sanskrit term *iṣṭa* may either mean "given" or "optional". With the former meaning the rule would imply the method of finding rational right angles having a given leg.

Brahmagupta was the first to give a solution of the equation $x^2 + y^2 = z^2$ in integers. His solution is

$$m^2 - n^2, 2mn, m^2 + n^2.$$

m and n being two unequal integers.²

Thus if $m=7$ and $n=4$, then $m^2 - n^2 = 33$, $2mn = 56$ and $m^2 + n^2 = 65$; then the three numbers 33, 56 and 65 bear the relation $33^2 + 56^2 = 65^2$.

Mahāvīra (850 A.D.) also states

The difference of the squares (of two elements) is the upright, twice their product is the base and the sum of their squares is the diagonal of a *generated* rectangle.²

Isosceles Triangles with Integral Sides : The following statement of Brahmagupta in this connection is very significant :

1. इष्टस्य मुजस्य कृतिर्भक्तो नेष्टेन तद्वत् कोटिः ।

आयतचतुरस्रस्य द्वे त्रस्येष्टाधिका कर्णः ॥

—BrSpSi. XII. 35

2. GSS. VII. 90½

The sum of the squares of two unequal numbers is the side; their product multiplied by two is the altitude, and twice the difference of the squares of those two unequal numbers is the base of an isosceles triangle.¹

Thus if m, n be two integers such that m is not equal to n , the sides of all rational isosceles triangles with integral sides are given by

$$m^2 + n^2, m^2 + n^2, 2(m^2 - n^2)$$

and the altitude of the triangle is $2mn$.

This method was also followed by Mahāvīra and other Indian mathematicians. In fact, their solutions are based on the juxtaposition of two rational right triangles, equal so that they have a common leg. It is remarkably a powerful device, for every rational triangle or quadrilateral may be formed by the juxtaposition of two or four rational right triangles.

Isosceles Triangles with a Given Altitude

Here we have a rule given by Brahmagupta for finding out all rational isosceles triangles possessing the same altitude :

The (given) altitude is the producer (*karana*). Its square divided by an optional number is increased and diminished by that optional number. The smaller is the base and half the greater is the side.²

Thus if m be any rational number then for a given definite altitude a , the sides of the rational isosceles triangles are $\frac{1}{2}\left(\frac{a^2}{m} + m\right)$ each and the base is $\frac{a^2 - m^2}{m}$. We shall illustrate it by an example taken from the commentary of Pṛthūdaka Svāmī. The given altitude is 8; let us take any rational number $m=4$ then the two equal sides of the isosceles are given by $\frac{1}{2}\left(\frac{8^2 + 4^2}{4}\right) = 10$ each and the base is $\frac{8^2 - 4^2}{4} = 12$. Thus the three sides of the

1. कृति युतिर सदृशराशयोर्बाहुर्धोतो द्विसंयुषो लम्बः ।

कृत्यन्तरमसदृशयोर्द्विगुणं द्विसमन्विमुज भूमिः ॥

—BrSpSi. XII. 33

2. करणी लम्बस्तत्कृतिरिच्छतेष्वेन संयुताऽल्पा भूः ।

अधिको द्विह तो बाहुः संवे प्यो यद्वयो कर्माः ॥

—BrSpSi. XII. 37.

rational isosceles triangle with altitude 8 are (10,10, 12).

Rational Scalene Triangles: Brahmagupta lays down the following rule in the case of rational scalene triangle ;

The square of an optional number is divided twice by two arbitrary numbers; the moieties of the sums of the quotients and (respective) optional numbers are the sides of a scalene triangle; the sum of the moieties of the differences is the base.¹

In other words, if m, p, q are any rational numbers, then the sides of a rational scalene triangle are :

$$\frac{1}{2} \left(\frac{m^2}{p} + p \right), \quad \frac{1}{2} \left(\frac{m^2}{q} + q \right), \\ \frac{1}{2} \left(\frac{m^2}{p} - p \right) + \frac{1}{2} \left(\frac{m^2}{q} - q \right)$$

Here the altitude (m), area and segments of the base of this triangle are all rational.

Thus putting $m=12$, $p=6$, and $q=8$ in Brahmagupta's general equation, Pṛthūdaka Svāmī derives a scalene triangle with sides (13,15) and (14) altitude (12), area (84 and the segments of the base (5) which are all integral numbers.

$$\frac{1}{2} \left(\frac{m^2}{p} + p \right) = \frac{1}{2} \left(\frac{12^2}{6} + 6 \right) = 15;$$

$$\frac{1}{2} \left(\frac{m^2}{q} + q \right) = \frac{1}{2} \left(\frac{12^2}{8} + 8 \right) = 13$$

Fig. 19

Fig. 20

1. इष्टद्वयेन भक्तो द्विषेष्ट वर्गं फलेष्टयोगावै ।
विषमत्रिभुजस्य भुजाविष्टोनफलार्थयोगो भूः ॥

Thus the two sides of the rational scalene triangle are 15 and 13. The base is .

$$\frac{1}{2} \left(\frac{12^2}{6} - 6 \right) + \frac{1}{2} \left(\frac{1^2}{8} - 8 \right) = 9 + 5 = 14$$

The altitude is $m=12$; area is equal to $\frac{\text{base} \times \text{altitude}}{2}$

$$= \frac{14 \times 12}{2} = \text{and the segments are } \sqrt{13^2 - 12^2} = 5 \text{ and}$$

$$\sqrt{(15^2 - 12^2)} = 9. \text{ Thus they are all integers.}$$

Rational Isosceles Trapeziums

Brahmagupta has given us a method of obtaining such isosceles trapeziums whose sides, diagonals, altitude, segments and area are all rational numbers. His rule is as follows :

The diagonals of the rectangle (generated) are the flank sides of an isosceles trapezium; the square of its side is divided by an optional number and then lessened by that optional number and divided by two; (the result) increased by the upright is the base and lessened by it is the face.¹

Fig. 21

Here in the figure, we have the isosceles trapezium ABCD of which CD is the base and AB is known as the face. According to Brahmagupta's rule, we have (p being the optional number).

$$CD = \frac{1}{2} \left(\frac{4m^2n^2 - p}{p} \right) + (m^2 - n^2) \quad (\text{base})$$

$$AB = \frac{1}{2} \left[\frac{4m^2n^2}{p} - p \right] - (m^2 - n^2) \quad (\text{face})$$

$$DH = (m^2 - n^2) \quad (\text{upright})$$

1. आहतकर्षो वाह्यं मुजङ्गतिरिष्टेन भावितेष्टोना ।

दिहता कोव्यधिका भूमिं खमना दिसमचतुरस्रे ॥

$$AD = BC = m^2 + n^2 \quad (\text{the sides of the trapezium})$$

$$HC = \text{base-upright} = \frac{1}{2} \left[\frac{4m^2n^2}{p} - p \right] \quad (\text{segment})$$

$$AC = BD = \left[\frac{4m^2n^2}{p} + p \right] \quad (\text{diagonal})$$

$$AH = 2mn \quad (\text{altitude})$$

$$ABCD = mn \left[\frac{4m^2n^2}{p} - p \right] \quad (\text{area})$$

By choosing the values of m , n and p suitably, the values of all the dimensions of the isosceles trapezium can be made integral. Prthūdaka Svāmī starts with the rectangle (5, 12, 13) and suitably takes p as 6; then he calculates out the dimensions of the trapezium: flank sides (AD and BC) = 13, base = 14, and base = 4, altitude (AH) = 12, segments of base (DH and HC) = 5, and 9, diagonals (AC and BD) = 15, area $ABCD$ = 108. All these values are integers.

In this example, the rectangle chosen is (5, 12, 13) which is $AA'DH$, where $AD = m^2 + n^2 = 13$

$$\text{and } DH = m^2 - n^2 = 5$$

whence by adding the two we have

$$2m^2 = 18$$

This gives the value of $m = 3$, and hence $n = 2$. Prthūdaka Svāmī has taken the value of $p = 6$ by choice. Putting these values of m , n and p , the values for the dimensions of the isosceles trapezium follow from the expressions given by Brahmagupta.

$$CD = \frac{1}{2} \left(\frac{4 \cdot 3^2 \cdot 2^2}{6} - 6 \right) + \left(3^2 - 2^2 \right) = 9 + 5 = 14 \text{ (base)}$$

$$\text{Face} = 9 - 5 = 4$$

$$\text{Sides } AD = BC = 3^2 + 2^2 = 13$$

and so on for the other dimensions.

Rational Trapeziums With Three Equal Sides

This problem is very much the same as one of the rational isosceles trapezium with the only difference that in this case one of the parallel sides is also equal to the slant sides. We

have the following solution of this problem from Brahmagupta :

The square of the diagonal (of a *generated* rectangle) gives three equal sides; the fourth (is obtained) by subtracting the square of the upright from thrice the square of the side (of that rectangle). If greater, it is the base; if less, it is the face.¹

As before, the rectangle generated from m, n is given by $(m^2 - n^2, 2mn, m^2 + n^2)$, that is these are the three sides of the right triangle, which correspond to the two sides and the diagonal of the rectangle generated by them. Let us suppose, we have a trapezium ABCD whose sides AB, BC and AD are equal, then

$$AB = BC = AD = (m^2 + n^2)^2$$

$$CD = 3(2mn)^2 - (m^2 - n^2)^2 = 12m^2n^2 - m^4 - n^4$$

$$\text{or } CD = 3(m^2 - n^2)^2 - (2mn)^2 = 3m^4 + 3n^4 - 10m^2n^2.$$

Prthūdaka Svāmī has taken an illustration, where $m=2$, $n=1$ and he deduces two rational trapeziums with three equal sides (25, 25, 25, 39) and (25, 25, 25, 11).

The segment (CH), altitude (AH), diagonals (AC, BD) and area of this trapezium are also rational, and given by :

$$CH \text{ (segment)} = 6m^2n^2 - m^4 - n^4$$

$$AH \text{ (altitude)} = 4mn(m^2 - n^2)$$

$$AC = BD \text{ (diagonals)} = 4mn(m^2 + n^2)$$

$$ABCD \text{ (area)} = 32m^3n^3(m^2 - n^2).$$

Rational Inscribed Quadrilaterals

We find in the *Brahmasphuṭasiddhānta* a remarkable proposition formulated by Brahmagupta :

To find all quadrilaterals which will be inscribable within circles and whose sides, diagonals, perpendiculars, segments (of sides and diagonals by perpendiculars from vertices as also of diagonals by their intersection), areas, and also the diameters of the

1. कर्षकृतिस्त्रिसम मुखास्त्रयश्चतुर्थो विरोधो कोटि कृतिम् ।

बाह्यकृतेस्त्रिमुखया वचनिको भूमुर्खं द्विनः ॥

circumscribed circles will be expressible in integers. Such quadrilaterals we shall call as *Brahmagupta Quadrilaterals*.

The solution of this formidable problem has been given by Brahmagupta as follows :

The upright and bases of two right-angled triangles being reciprocally multiplied by the diagonals of the other will give the sides of a quadrilateral of unequal sides : (of these) the greatest is the base, the least is the face, and the other two sides are the two flanks.¹

Taking Brahmagupta's integral solution, the sides of the two right triangles of reference are given by :

$$(1) \quad m^2 - n^2, 2mn, m^2 + n^2;$$

$$(ii) \quad p^2 - q^2, 2pq, p^2 + q^2;$$

where m, n, p, q are integers. Then the sides of the *Brahmagupta Quadrilateral* are.

$$(m^2 - n^2)(p^2 + q^2), (p^2 - q^2)(m^2 + n^2), \\ 2mn(p^2 + q^2), 2pq(m^2 + n^2) \quad (\text{Arrangement A})$$

Prthudaka Svāmī has illustrated the rational inscribed quadrilateral by taking an example of the right angle triangles.

$$(i) \quad (3, 4, 5) (m^2 - n^2 = 3, \\ m^2 + n^2 = 5, \text{ whence } \\ m = 2, n = 1)$$

$$(ii) \quad (5, 12, 13) (p^2 - q^2 = 5, \\ p^2 + q^2 = 13, \text{ whence } \\ p = 3, q = 2)$$

Fig. 22

Substituting these values in the above equations, we get the sides of the quadrilateral as (39, 25, 52 and 60).²

1. जाल्यद्वय कोटिमुजाः परकर्णगुणा मुजाश्चतुर्विधमे ।

अधिको भूमु खदीनो बाहुदितयं मुजाक्यौ ॥

—BrSpSi. XII. 38

2. The diagonals of this quadrilateral are given by Bhāskara II as 56 (= 3.12 + 4.5) and 63 (= 4.12 + 3.5).

(Cont. on page 268)

Put in other words, this means that one has to solve the following equations :

$$(i) \quad 5x-25 = y^2$$

$$(ii) \quad 10x-100 = y^2$$

$$(iii) \quad 83x-7635 = y^2$$

Prthūdaka Svāmī, the commentator on the *Brāhmasphuṭa-siddhānta* proceeds to solve these equations as follows :

(1.1) Suppose $y = 10$; then $x = 125$. Or put $y = 5$; then $x = 10$.

(2.1) Suppose $y = 10$; then $x = 20$.

(3.1) Assume $y = 1$; then $x = 92$.

He then remarks that by virtue of the multiplicity of suppositions there will be an infinitude of solutions in every case, But no method has been given either by Brahmagupta or his commentator to obtain the general solution.

Double Equations of the First Degree

Perhaps we have the earliest reference of the simultaneous indeterminate quadratic equations of the type

$$x \pm a = u^2$$

$$x \pm b = v^2$$

in the *Bhaskārī Manuscript* (Folio 59, recto).

Brahmagupta gives the solution of such simultaneous indeterminate quadratic equations of a general case as follows :

The difference of the two numbers by the addition or subtraction of which another number becomes a square, is divided by an optional number and then increased or decreased by it. The square of half the result diminished or increased by the greater or smaller (of the given number) is the number (required).¹

Expressed in the language of algebra, shall have :

$$= \frac{1}{4} \left\{ \frac{1}{2} \left(\frac{a-b}{m} \pm m \right) \right\}^2 \mp a$$

1. यास्यां कृतिरधिको नस्तदन्तरं हत युतो न मिष्टेन ।

तद्वल कृतिरधिको नऽधिको रधिको न यो राशिः ॥

$$\text{or } x = \left\{ \frac{1}{2} \left(\frac{a-b}{m} \mp m \right) \right\}^2 \mp b$$

where m is an arbitrary number.

Datta and Singh has given the *rationale* of this method as follows :

$$u^2 = x \pm a; v^2 = x \pm b,$$

$$\text{From them, we have } u^2 - v^2 = \pm a \mp b$$

$$\text{Therefore } u - v = m$$

$$\text{and } u + v = \frac{\pm a \mp b}{m},$$

where m is arbitrary. Hence

$$u = \frac{1}{2} \left(\frac{\pm a \mp b}{m} + m \right) = \pm \frac{1}{2} \left(\frac{a-b}{m} \pm m \right)$$

Since it is obviously immaterial whether u is taken as positive or negative, we have

$$u = \frac{1}{2} \left(\frac{a-b}{m} \pm m \right)$$

$$\text{Similarly } v = \frac{1}{2} \left(\frac{a-b}{m} \mp m \right)$$

$$\text{Therefore } x = \left\{ \frac{1}{2} \left(\frac{a-b}{m} \pm m \right) \right\}^2 \mp a,$$

$$\text{or } x = \left\{ \frac{1}{2} \left(\frac{a-b}{m} \mp m \right) \right\}^2 \mp b,$$

where m is an arbitrary number.

Now we shall take up another particular case, for which Brahmagupta has given a rule :

The sum of the two numbers the addition and subtraction of which make another number (severally) a square, is divided by an optional number and then diminished by that optional number. The square of half the remainder increased by the subtractive number is the number (required)¹.

In the algebraic notations, we shall express it as follows :

1. यैरुनो यैश्च युतो रूपैर्वर्गस्तदैवयमिष्टं हृतम् ।

इष्टोनं तद्वल कृतिरुनाऽभ्यधिका भवति राशिः ॥

—BrSpSi. XVIII. 71

$$y = \frac{1}{a} \left(\frac{ad+bc}{m} + b \right)$$

if $b > c$ and $m > \frac{ad+bc}{m}$. If these conditions be reversed then x and y will have their values interchanged.

Datta and Singh have given the following *rationale* of these solutions :

$$axy = bx + cy + d,$$

$$\text{or } a^2xy - abx - acy = ad,$$

$$\text{or } (ax-c)(ay-b) = ad+bc.$$

Suppose $ax-c=m$, a rational number;

$$\text{then } ay-b = \frac{ad+bc}{m}.$$

Therefore,

$$x = \frac{1}{a}(m+c)$$

$$y = \frac{1}{a} \left(\frac{ad+bc}{m} + b \right)$$

Or, we may put $ay-b=m$;

in that case, we shall have $ax-c = \frac{ad+bc}{m}$;

$$\text{whence } x = \frac{1}{a} \left(\frac{ad+bc}{m} + c \right),$$

$$y = \frac{1}{a}(m+b).$$

Brahmagupta's own rule.

Whilst the rule given above is ascribed to an unknown author, Brahmagupta's own rule for the solution of a quadratic indeterminate equation involving a factum is as follows :

With the exception of an optional unknown, assume arbitrary values for the rest of the unknowns, the product of which forms the factum. The sum of the product of these (assumed values) and the (respective) coefficients of the unknowns will be absolute quantities. The continued products of the assumed values and of the coefficient of the factum will be the coefficient of the optionally (left out) unknown. Thus the solution

is effected without forming an equation of the factum
Why then was it done so ?¹

Datta and Singh think that the reference in the latter portion of this rule is to the method of the unknown author :

"*Kim krtam tadatah*" ? The principle underlying Brahmagupta's method is to reduce, like the Greek Diophantus (c.275 A.D.), the given indeterminate equation to a simple determinate one by assuming arbitrary values for all the unknowns except one. So undoubtedly it is inferior to the earlier method.

We now take an illustrative example from Brahmagupta :

On subtracting from the product of signs and degrees of the Sun, three and four times (respectively) those quantities, ninety is obtained. Determining the Sun within a year (one can pass as a proficient) mathematician.

If we presume x to denote the signs and y the degrees of the Sun, then the equation would be :

$$xy - 3x - 4y = 90$$

Prthudaka Svāmī solves it in two ways :

(i) Let us assume the arbitrary number to be 17. then

$$x = \frac{1}{2} \left(\frac{90.1 + 3.4}{17} + 4 \right) = 10$$

$$y = \frac{1}{2} (17 + 3) = 10$$

(ii) Let us assume arbitrarily $y = 20$. On substituting this value of y in the above equation, we get

$$20x - 3x = 170$$

$$\text{whence } x = 10.$$

Arabic and Indian Divisions of the Zodiac

It has long been a debated question whether the Indian and Arabian divisions of the zodiac had a common origin. Sir William Jones thought that they had not; but Colebrooke holds a contrary view. The coincidence, in the two systems of division is so exact that he thinks, it could not be due to chance. Colebrooke has discussed this point in details in one of his Papers entitled "On the Indian and Arabian divisions of the zodiac", *Asiatic Researches* Vol. ix. p. 323-376, reproduced in the *Miscellaneous Essays*, Vol. II, p. 321-373, 1872.

1. *Āsvini*, now the first *nakṣatra*, but anciently, the last but one, probably obtained its present situation at the head of the asterisms, when the beginning of the zodiac was referred to the first degree of *Meṣa* (the Ram). As measuring a portion of the zodiac, it occupies the first $13^{\circ}20'$ of *Meṣa*; and its beginning follows immediately after the principal star in the last *nakṣatra* *Revati*, reckoned by some exactly, by others nearly, opposite to the very conspicuous one, which forms the fourteenth asterism. As a constellation, *Āsvini* comprises three stars (Aries α , β , γ) figured as a horse-head; and the principal, which is also the northern one, is stated by all ancient authorities, in 10° N and 8° E. from the beginning of the *Meṣa*.

According to Arabs, the first *manzil* or lunar mansion is entitled *Sheratan*, (by Persians, *Sheratain*) and comprises two stars of the third magnitude on the head of Aries, in lat. $6^{\circ}36'$ and $7^{\circ}51'$ N and long. $26^{\circ}13'$ and $27^{\circ}7'$. With the addition of a

third, also in the head of the Ram, the asterism is denominated *Āshrait*. The bright star of the second or third magnitude which is out of the figure of the Ram, according to Ulugh Beg, but on the nose according to Hipparchus, cited by this author from Ptolemy, is determined *Nātih* : It is placed in lat. $9^{\circ}30'N$ and long. $1^{\circ}0'43'$, and is apparently the same with the principal star of the Indian asterism; for Muhammad of Tizin, in his table of declination and right ascension, expressly terms it the first star of the *Sheratain*.

2. *Bharani*, the second asterism, comprises three stars (35, 39, 41 Aries) figured by the *yonī* or *pudendum muliebre* and the principal and southern star of this *nakṣatra* is placed in $12^{\circ}N$. On the Arabian system, the second manzil, entitled *Butain* is placed by Ulugh Beg in lat. $1^{\circ}12'$ and $3^{\circ}12'$, and this cannot possibly be reconciled with the Indian constellation. But Muhammad of Tizin assigns to the bright star of *Butain* a declination of $23^{\circ}N$ exceeding by nearly 2° the declination allotted by him to *Nātih* or his first star in *Sheratain*. This agrees with the difference between the principal stars of *Āsvini* and *Bharani*; and it may be inferred, that some among the Mohammadan astronomers have concurred with the Hindus, in referring the second constellation to stars that form Musca.

3. *Kṛttikā*, now the third, formerly the first, *nakṣatra* consists of six stars figured as knife or razor, and the principal and southern star is placed in $4\frac{1}{2}^{\circ}$ or $5^{\circ}N$ and in 65 sixths of degrees (or $10^{\circ}50'$) from its own commencement (cf. the *Sūryasiddhānta*), or $37^{\circ}28'$ to 38° from the beginning of the *Meṣa* (the *Siddhānta-Siromaṇi* or the *Graha Laghava*) respectively. This longitude of the circle of declination corresponds nearly with that of the bright star in the Pleiades, which is 40° of longitude distant from the principal star of *Revati*.

The stars indicated by Ulugh Beg for *Thurayyā*, also correspond exactly with the Pleiades.

4. *Rohiṇi*, is the fourth *nakṣatra*, the Arabic name for the fourth mansion is *Debarān* (or with the article *Aldebarān*). It corresponds to the bright star called the Bull's eye, and which is unquestionably the same with the principal and eastern star of *Rohiṇi*, placed in $4\frac{1}{2}^{\circ}$ or $5^{\circ}S$ and $49\frac{1}{2}^{\circ}E$ by the Hindu writers on Astronomy. This *nakṣatra* is

figured as a wheel cart, and comprises five stars, out of the seven which the Greeks named the Hyades. The Arabs, however, like the Hindus, reckon five stars only in the asterism. Sir William Jones supposes them to be in the head and neck of the Bull; they probably are $\alpha, \rho, \gamma, \delta, \epsilon$ Tauri, agreeably to Mons. Bally's conjecture.

5. *Mr̥gasiṛā*, the fifth *nakṣatra*, represented by an antelope head, contains three stars; the same which constitute the fifth lunar mansion *Hakāh*; for the distance of 10° S assigned to the northern star of this *nakṣatra*, will agree with no other but one of the three in the head of Orion. The difference of longitude (24° to $25\frac{1}{2}^{\circ}$) from *Kṛttikā* corresponds with sufficient exactness; and so does the longitude of its circle of declination (62° to 63°) from the end of *Rewatī*; since the true longitude of λ Orionis, from the principal star in *Revatī* (ζ piscium) is $63\frac{1}{2}^{\circ}$.

6. *Ārdṛā*, the sixth *nakṣatra*, consists of a single bright star, described as a gem, and placed in 9° S (by some in 11°) and at the distance of $4\frac{1}{2}$ to 4° in longitude from the last asterism. This indicates the star in the shoulder of Orion (α orionis). The sixth lunar mansion, is named by the Arabs as *Hanāh*; and comprises two stars in the feet of the second twin, according to Ulugh Beg, though others make it to be a shoulder. Mohammad of Tizin allots five stars to this constellation; and the Kāmūs, among various meanings of *Hanāh*, says, that it is a name for five stars in the left arm of Orion; remarking also, that the lunar mansion is named *Tahāyi*, comprising three stars called *Tahyāt*. Obviously here the Indian and Arabian asterisms are irreconcilable.

7. *Punarvasū* (used in a dual number) is the seventh *nakṣtra*, and is represented by a house, or even a bow, and it includes four stars, among which the principal and eastern one is 30° or 32° from the fifth asterism; but has been placed by all authorities in 6° N. This agrees with (β Geminorum) one of the two stars in the heads of the Twins, which together constitute the seventh lunar mansion *ziraā*, according to Mohammad of Tus and Mohammad of Tizin and other Arabian authorities. The seventh lunar mansion of Arabs is named *ziraā ul ased* according to Jauhari and other cited by Hyde in his *Commen-*

tary on Ulugh Beg. and that the *Kamūs* makes this term to be the name of eight stars in the form of a bow.

8. *Puṣya*, the eighth asterism, is described as an arrow, and consists of three stars, the chief of which being also the middle most, has no latitude, and is 12° to 13° distant from the seventh asterism, being placed by Hindu astronomers in 106° of longitude. This is evidently δ Cancer, and does not differ widely from the eighth lunar mansion *Nethrah*, which according to Ulugh Beg and others consists of two stars, including the nebula of Cancer. The Indian constellation comprises two other stars besides δ Cancer, which are perhaps γ and β of the same constellation.

9. *Asleṣa*, the ninth asterism, contains five stars figured as a potter's wheel, and of which the principal or eastern one is placed in 7° S, and according to different tables, 107° , 108° or 109° E. This appears to be intended for the bright star in the southern claw of Cancer (α Cancer), and cannot be reconciled with the lunar mansion *Tarf* or *Tarfah*, which comprises two stars near the lion's (simha) eye, the northernmost being placed by Mohammad of Tizin in 24° of N. declination.

10. *Maghā*, the tenth asterism, contains like the last, five stars, but which are figured as a house. The principal of the Southern one has no latitude; and according to all authorities, has 129° longitude. This is evidently Regulus (α Leonis): which is exactly 129° distant from the last star in *Revati*. The tenth lunar mansion of Arabians is *Jebhah*, which comprises three (some say, four) stars, nearly in the longitude of the lion's heart. In this instance, therefore, the Indian and Arabian divisions of the zodiac coincide. This *nakṣatra* consists of α , γ , δ and ν Leonis.

11. *Pūrva-Phalguni* is the eleventh *nakṣatra* and is represented by a couch or bedstead; it consists of two stars determined by the place of the chief star (the northernmost, according to the *Sūrya-Siddhānta*) in 12° N and 144° E, or according to Brahmagupta, the *Śrōmanī* and the *Grahalāghava* 147° or 148° E. They are probably δ and θ Leonis. The Arabian name for this lunar mansion is *zubrah* or *Khertān*.

It may be mentioned here that Brahmagupta and Bhāskara selected the southern for the principal star; while the *Sūrya-Siddhānta* took the northern. Hence the latitude stated by several Hindu authorities is the mean between both stars; and the difference of longitude, compared to the preceding and subsequent asterisms, may be exactly reconciled upon this supposition.

12. *Uttara-Phālgunī*, which is the twelfth *nakṣatra*, consists of two stars, and is figured as a bed or cot. These stars are ascertained by the place of one of them (the northernmost) 13° N. and 155° E. This indicates β Leonis; the same which singly constitutes the Arabian Lunar mansion *Serfah*, though Mohamad of Tizīn seems to hint that it consists of more than one star.

13. *Hasta*, the thirteenth *nakṣatra*, has the name and figure of a hand; and is suitably made to contain five stars. The principal one towards the west, next to the north-western star, is placed according to all authorities in 11° and 170° E. This can only belong to the constellation Corvus; and accordingly five stars in that constellation (α , β , γ , δ and ϵ Corvi). The thirteenth lunar mansion of Arabs is *Awwa*, which is also described to contain five stars, situated under Virgo and so disposed as to resemble the letter *Alif*. They are placed by Ulugh Beg in the wing. Here obviously, there is nothing common between the Hindu and Arabian specification of the asterism. The agreement is only in the number of stars and in the longitude.

14. *Citrā*, the fourteenth *nakṣatra*, is figured as pearl. It is placed by the *Sūrya-Siddhānta* in 2° S and 180° E. and by Brahmagupta, the *Śiromaṇi* and *Grahalāghava* in $1\frac{3}{4}$ or 2° S and 183° E. This agrees with the Virgin's spike (α Virginis). The same star constitutes the fourteenth lunar mansion of the Arabs named from it *Simāc ul aāzi*.

15. *Svāti*, the fifteenth *nakṣatra*, is represented by a coral bead. The *Sūrya-Siddhānta*, Brahmagupta, the *Śiromaṇi* and *Grahalāghava*, all concur in placing it at 37° N. They differ one degree in longitude of its circle of declination, three of them

making it 199° and the other 198° . The Indian asterism totally disagrees with the lunar mansion *Ghafr* which is the fifteenth Arabian mansion, and which consists of three stars in the Virgin's (*Kanyā*) foot, according to Ulugh Beg. but in or near the balance (*Tulā*), according to others.

16. *Viśākhā*, the sixteenth *nakṣatra*, consists of four stars described as a festoon. All the authorities place the principal and northernmost star in $1^\circ, 1^\circ 20'$ or $1^\circ 30'$ S and in $212^\circ, 212^\circ 5'$ or 213° E. The latitude seems to indicate the bright star in the Southern Scale (α Librae), though the longitude disagrees (suggesting possibly a remote star κ Librae). Colebrooke suggests the four stars to be α ν ι Librae and γ Scorpii. The sixteenth lunar mansion according to Arabs is *Zubānah* or *Zubāniyah* according to Mohammad of Tizin, the bright star in the northern scale (β Librae).

17. *Anurādhā*, the seventeenth *nakṣatra*, consists of four stars and is described as a row of oblations in a right line. Its chief or middlemost star is placed in 3° , or 2° or $1^\circ 45'$ S and in 224° or $224^\circ 5'$ E, thus placing it near the head of the Scorpion (*Vṛścika*) (δ Scorpionis) and the asterism comprises β , δ , π , and ρ Scorpionis. The seventeenth lunar mansion of Arabs is called *Iklil* or *Iklilul-jebbah*, which is said to contain 4, 3, or 6 stars lying in a straight line. Those assigned by Ulugh Beg for this mansion are β , δ , ν and π Scorpionis. Thus here the Indian and Arabian astronomers both concur exactly.

18. *Jyesthā*, the eighteenth *nakṣatra*, comprises three stars figured as a ring. The principal and middlemost star is placed in $4^\circ 3\frac{1}{2}'$ or 3° S and in $229^\circ, 229^\circ 5'$ or 230° E; this position indicates Antares or the Scorpion's heart (α Scorpionis), which is also the eighteenth lunar mansion, named *Kalb* or *Kalbul'akrab*. The three stars of Indian asterism may be α , σ and τ Scorpionis.

19. *Mūla*, the nineteenth *nakṣatra*, is represented by a lion's tail and it contains eleven stars, of which the characteristic one, the easternmost, is placed in $9^\circ, 8\frac{1}{2}'$ or 8° S and in 241° or 242° E. This probably (not exactly) indicates ν Scorpionis. This agrees with the eighteenth lunar mansion of Arabs known as *Shaulah*, consisting of two stars near the Scorpion's

sting. The Hindu asterism probably includes all the stars in the Scorpion's tail (ϵ , μ , ζ , η , θ , ι , κ , λ , ν and ν Scorpionis).

20. *Pūrva-Āṣāḍha*, the twentieth *nakṣatra*, is figured as an elephant's tooth or as a couch, and it consists of two stars, of which the most southern one is placed in $5\frac{1}{2}^{\circ}$, $5\frac{1}{3}$ or 5° S and 254° or 255° E. This corresponds well with δ Sagittarii, and which also corresponds with the twentieth lunar mansion of Arabs called *Nāaim*. The Arabian mansion consists of four, or according to some eight, stars. The Indian *nakṣatra* corresponds to δ and ϵ Sagittarii.

22. *Uttara-Āṣāḍha*, the twenty-first *nakṣatra*, is represented by a couch or by an elephant's tooth. The principal or the most northerly star is placed in 5° S and 260° or 261° E, agreeing with a star in the body of Sagittarius (τ Sagittarii), and the other star is perhaps the one marked ζ . The Arabian lunar mansion corresponding to it is *Baldah*, consisting of six stars, two, of which are placed by Mohammad of Tizīn in declination 21° and 16° . One of these must be a star in the head of Sagittarius. Some authors, on the contrary, describe the lunar mansion as destitute of stars. Here the Arabs and Hindus do not show reconciliation.

22. *Abhijit*, the twenty-second asterism, consists of three stars figuring as a triangle or as a nut of floating Trapa (in modern Indian astronomy, it does not occupy an equal portion of the ecliptic with other *nakṣatras*). Its brightest star is very remote from the zodiac, being in 60° or 62° N. The longitude of its circle of declination is 265° , $266^{\circ} 40'$ or 268° according to different authorities. The corresponding lunar mansion of Arabs is *Zābih*, consisting of two stars (according to some, four) in the horns of Capricorn. This totally disagrees with Indian asterism.

20. *Śravaṇa*, the twenty-third *nakṣatra*, is represented by three footsteps, and contains three stars of which the middlemost is placed in 30° N (all authorities agree), and longitude 280° (*Sūrya-Siddhānta*) or 278° (Brahmagupta and *Śiromaṇi*), or 275° (*Grahalāghava*). The assigned latitude indicates the bright star in the Eagle, whence the three may be inferred to be α , β

and γ Aquilae. According to Arabs, the twenty-third lunar mansion is *Bala*, which consists of two stars in the left hand of Aquarius. Here again Arabian and Hindu divisions are at variance.

24. *Dhaniṣṭhā*, the twenty-fourth *nakṣatra*, is represented by a drum or tabor. It comprises four stars, the westernmost of which is placed in 36° N and according to Brahmagupta, *Śiromaṇi* and the *Śūrya-Siddhānta* in 290° E (*Grahalāghava* gives 286°). This longitude of the circle of declination and the distance of the star on it from the ecliptic indicate the Dolphin : and the four stars are α , β , γ and δ Dolphini. The corresponding lunar mansion of Arabs is *Saud*, which comprises two stars in Aquarius (β and ζ Aquarii). Here again the two divisions disagree completely.

24. *Śatahbīṣak*, the twenty fifth *nakṣatra*, is a cluster of 100 stars figured by a circle. The principal or the brightest has no latitude; or only a third, or at utmost half, a degree of south latitude; and longitude 320° . This best corresponds with λ Aquarii. According to Arabs, the twenty-fifth lunar mansion is known as *Akhbiyah* which consists of three stars only, placed in the wrist of the right hand of Aquarius. However, it appears from Ulugh Beg's tables, as well as from Mohammad of Tizīn's, that four stars are assigned to this mansion. The Indian and Arabian systems of division differ considerably but less widely according to some.

26. *Pūrva-Bhādrapada*, the twenty-sixth *nakṣatra*, consists of two stars represented by a couch or bed, or else by a double headed figure, one of which is placed in 24° N and 325° or 326° E. The only conspicuous star nearly in that position is the bright star in Pegasus (α Pegasi) and the other may be the nearest considerable star in the same constellation (ζ Pegasi). The twenty-sixth Arabian lunar mansion is *Mukaddim*, consisting of two brightest stars in Pegasus (α and β). Here the Indian and Arabian divisions show concurrence.

27. *Uttar-Bhādrapada*, the twenty-seventh *nakṣatra*, consists of two stars, figured as a twin or a person with double face, or else as a couch. The position of the most northerly of the two

is in 26° or 27° N and 337° E, which probably indicates the bright star in the head of Andromeda, and the other star to be the one in the extremity of the wing of Pegasus (γ Pegasi). This exactly agrees with the twenty-seventh lunar mansion of Arabs named as *Muakkher*. Ulugh Beg assigns those stars to it.

28. *Revati*, the twenty-eighth *nakṣatra*, comprises thirty-two stars figured as a tabor. The principal star is the southernmost one, it has no latitude, and two of them assert no longitude, but some make it ten minutes short of the origin of the ecliptic, viz. $359^{\circ} 50'$. This clearly marks the star on the ecliptic in the string of the Fishes (ζ Piscium). The ascertainment of this star is important in regard to the adjustment of the Hindu sphere. The Arabic name for this mansion is *Risha*, signifying a cord. But the constellation as described by Jauhari and cited by Golius, consists of a multitude of stars in the shape of a fish and termed *Betnu'lhūt*; in the navel of which is the lunar mansion. Mohammad of Tizin also makes this lunar mansion to be the same with *Betnu'lhūt*, which appears, however, to be the bright star in the girdle of Andromeda (β Andromedae) though others describe it as the northern fish, extending, however, to the horns of Ram. The lunar mansion and the Indian asterism, therefore, are not reconcileable in this last instance.

I leave it to the readers to draw an inference as to the concurrence of the divisions of zodiac in Indian and Arabian systems. I would personally agree with Sir William Jones that the agreements are by chance. Arabs derived the idea of dividing zodiac in 27 or 28 mansions from Indians, or may have got it from Greeks, and then they proceeded in their own way for details. I do not agree with those scholars who sometimes state that the Hindus took the hint of dividing the ecliptic from Greeks. The *Atharvaveda* devotes a number of Sūktas or hymns on Nakṣatras, and I have shown elsewhere that inspired by these hymns, Gārgya was the first Ṛṣi who detailed out the *nakṣatras*. This happened much before Greeks developed even their first notions of astronomy. While the concept of 27 *nakṣatras* is Vedic and most ancient and of purely Indian origin the concept of 12 Rāśis (signs) or twelve constellations is probably inspired from Greeks. [The names Kanyā, (virgo), Tula

(Libra), Vṛścika (Scorpio), Dhanu, (Sagittarius), Makara, (Capricorn), Kumbha (Aquarius), Mīna (pisces), Meṣa (Aries), Vṛṣa (Taurus), Mithuna (Gemini), Karka (Cancer), and Sīṁha (Leo) were not used for Rāśis or signs in the Vedic times]. I shall conclude this description with a passage from Colebrooke :

The result of comparison shows, I hope satisfactorily, that the Indian asterisms, which mark the divisions of the ecliptic, generally consist of nearly the same stars, which constitute the lunar mansions of the Arabians : but in a few instances, they essentially differ. The Hindus have likewise adopted the division of the ecliptic and zodiac into twelve signs or constellations, agreeing in figure and designation with those of the Greeks; and differing merely in the place of the constellations, which are carried on the Indian sphere a few degrees further west than on the Grecian. That the Hindus took the hint of this mode of dividing the ecliptic from the Greeks, is not perhaps altogether improbable; but if such be the origin of it they have not implicitly received the arrangement suggested to them, but have reconciled and adapted it to their own ancient distribution of the ecliptic into twenty-seven parts.

In like manner, they may have either received or given the hint of an armillary sphere as an instrument for astronomical observation ; but certainly they have not copied the instrument which was described by Ptolemy, for the construction differs considerably.

Names, Shapes, and Number of the Stars of the Nakṣatras

The *Muhūrta-cintāmaṇi* provides a list of shapes associated to the nakṣatras (*MuC.* II. 59-60). In this list we are giving the number of stars as indicated by Varāhamihira, Brahmagupta and Lalla. The identification given here is as indicated by E. Burgess, in his Translation of the *Sūrya-Siddhānta* 1935, p. 378. (Calcutta). This table has been reproduced here from the *Mahābhāskariya* of Bhāskara I, edited by K.S. Shukla.

Nakṣatra	Shape	Number of stars			Identification
		Varāha	Brahma	Lalla	
Aśvinī	Head of a horse	3	2	3	α, β, γ Aries
Bharanī	Yoni	3	3	3	35.39.41 Aries
Kṛttikā	Razor	6	6	6	η Tauri etc. (Pleiades)
Rohiṇī	Cart	5	5	5	$\alpha, \theta, \gamma, \delta, \varepsilon$ Tauri (Hyades)
Mṛgaśīrā	Head of a deer	3	3	3	$\lambda, \phi_1 \phi_2$ Orionis
Ārdrā	Jewel	1	1	1	α Crionis
Punarvasū	House	5	2	4	β, α, i, v, u Geminorum
Puṣya	Arrow-head	3	1	3	θ, δ, γ Cancrī
Āśleṣā	Wheel	6	6	5	$\varepsilon, \delta, \sigma, \eta, \rho$ Hydrae
Maghā	House	5	6	5	$\alpha, \eta, \varepsilon, \zeta, \eta, \nu$ Leonis
P-Phalgunī	Mañca	8	2	2	δ, θ Leonis
U-Phalgunī	Cot	2	2	2	β , 93 Leonis
Hasta	Hand	5	5	5	$\delta, \gamma, \varepsilon, \alpha, \beta$ corvi
Citrā	Pearl	1	1	1	α Virginis (Spica)
Svāti	Coral bead	1	1	1	α Bootis (Arcturus)
Viśākha	Arched doorway	5	2	4	$\varepsilon, \gamma, \beta, \alpha$, Librae
Anurādhā	Heaps of offerings to gods	4	4	4	δ, β, π Scorpionis
Jyēṣṭhā	Earpendent	3	3	3	α, σ, τ Scorpionis
Mula	Tail of a lion	11	2	11	$\lambda, \nu, \kappa, i, \theta, \eta, \zeta, \mu, \varepsilon$ Scorpionis
P-Āṣāḍha	Tusk of elephant	2	4	2	δ, ε Sagittarii
U-Āṣāḍha	Mañca	3	4	2	σ, ξ Sagittarii
Śravana	Three feet	3	3	3	α, β, γ Aquilae
Dhanīṣṭh	Drum	5	5	4	$\beta, \alpha, \gamma, \delta$ Delphini
Satabhiṣak	Circle	100	1	100	λ Aquarii etc.
P-Bhādra	Mañca	2	2	2	α, β Pegasi
U-Bhādra	Pair	8	2	2	γ Pegasi; α Andromedae
Revati	Drum	32	1	32	ζ Piscium etc.

CHAPTER XI

Brahmagupta's Astronomy : Its Highlights

Beginning or Starting Point

Very often in Indian astronomy, we come across a term *ahargana* (literally meaning collection of days), which means the number of mean civil days elapsed at mean Sunrise at *Laṅkā* on a given lunar day (*tithi*), since the beginning of *Kaliyuga*. It is the beginning of *Kaliyuga*, which is taken as the starting point for the reckoning of *ahargana*. This happened on Friday, February 18, B.C. 3102, at mean sunrise at *Laṅkā*, when the Sun, Moon, and the planets are supposed to have been in conjunction at the first point of the *nakṣatra* *Āśvini* (which is a fixed point situated near the star ζ-Piscium). According to Āryabhaṭa and Bhāskara I, the duration of *Kaliyuga* is 1,080,000 solar years. Four times this (4320,000) is the duration in solar years of a bigger unit called *Mahāyuga* or even *yuga*.

Laṅkā in Indian astronomy is a hypothetical place where the meridian of Ujjain (latitude 23° 11' N, longitude 75° 52' E from Greenwich) intersects the equator. It is one of the four hypothetical cities on the equator called *Laṅkā*, *Romaka*, *Siddhapur* and *Yamakoṭi* (or *Yavakoṭi*). The *Sūrya-siddhānta* describes *Laṅkā* as a great city (*mahāpuri*) situated on an island to the south of *Bhāratavarṣa*.¹ The present Ceylon is not the

1. समन्तान्मेरुमध्यात् तुल्यभागेषु तोयवेः ।
द्वीपेषु दिक्षु पूर्वादिनगर्यो देवनिर्मिताः ॥
भूवृत्त पादे पूर्वस्यां यवकोटौति विश्रुता ।
भद्राश्व वर्षे नगरी स्वर्णप्राकारतोरणा ।
यान्यायां भारतेवर्षे लङ्का तद्वन्महापुरी ॥

astronomical Lankā, as it is about six degrees to the north of equator. The astronomical Lankā is mentioned by Brahmagupta in the beginning of his very first Chapter¹.

According to Brahmagupta all the four yugas of a *Catur-yuga* or *mahāyuga* are not of the equal duration :

Kaliyuga is of 432,000 years. *Dvāpara* of 864,000 years, *Tretā* of 1,296,000 years and *Kṛtayuga* of 1,728,000 years; total of the four is 4,320,000 years. Āryabhaṭa regards all *yugas* of equal duration, 1,080,000 years².

The Saka era, which is usually used in Indian astronomy for the reckoning of years commenced 3179 years after the beginning of *Kaliyuga*.

The number of lunar months in a *yuga* does not coincide with the number of solar months. Thus we have the conception of the *Intercalary months* : the number of intercalary months in a *yuga* denotes the excess of the number of lunar months in a *yuga* over the number of solar months in a *yuga*. Thus in a *yuga* we have

Lunar months	53,433,336
Solar months	51,840,000
Intercalary months	1,593,336
Lunar days	1,603,000,080
Civil days	1,577,917,500
Omitted lunar days	25,082,580

The number of omitted lunar days in a *yuga* is equal to the number of lunar days in a *yuga* minus the number of civil days in a *yuga*,

(Cont. from page 289)

Units of time

For the measurements of durations, it is necessary to have units of time. Brahmagupta gives the following units :¹

6 prāṇas or Asus	=1 Rkṣa-vināḍikā or nakṣatra-vighaṭikā or one <i>pala</i> (24 seconds)
60 palas	=1 ghaṭikā (24 minutes)
60 ghaṭikās	=1 divasa or dina (day) (24 hours)
30 dinas	=1 māsa (month)
12 māsas	=1 varṣa or year

Similar to the divisions of time, we have the divisions of an arc :²

Vikalā (or viliptā or viliptikā) =second of arc.

60 vikalās	=1 kalā (minute of arc)
60 kalās	=1 aṁśa (degree of arc)
30 aṁśas	=1 rāśi
12 rāśis	=1 bhagaṇa (complete circle, 360°)

Unlike Āryabhaṭa and others, who take kali, dvāpara, tretā, and kṛta of equal number of years, Brahmagupta regards kali consisting of 432,000 years, dvāpara twice of it, consisting of 864,000 years, tretā thrice of Kali consisting of 1,296,000 years and kṛta four times of kali consisting of thus 1,728,000 years, all the four to be making a *yuga* of 4,320,000 years.³ Further in the beginning of kṛta there is a *sandhyā* of 1728000/12 years (=144,000 years), and at the end of Kṛta, there is a *sandhyā* of 144,000 years; similarly in the beginning of tretā, we have a

1. प्राणैर्विनाडिकार्द्धी षडभिर्वटिका षष्ठ्या ।
षटिका षष्ठ्या दिक्सो दिक्सानां त्रिंशत् मासाः ॥ —BrSpSi. I. 6
2. मासा द्वादशवर्षं विकलालिप्तांशराशिभगणांतः ।

षष्टिर्नाडयो दिक्सषष्टिस्तु विनाडिका नाडी ॥ —Ārya. III. 1
शुद्धैराणि षष्टिर्विनाडिकार्द्धी षडेव वा प्राणाः ।
एवं काल विभागः क्षेत्र विभागस्तथा भगणात् ॥ —Ārya, III. 2
3. स्वचतुष्टयरदवेदा रवि वर्षाणां चतुयुगं भवति ।
सन्ध्या सन्ध्यांशैः सह चत्वारि पृथक् कृतादीनि ॥
युगदशभागो युष्मिन्तः कृतं चतुर्भिस्त्रिभिर्गुणस्त्रेता ।
द्विगुणो द्वापरमेकेन संगुणः कलियुगं भवति ॥ —BrSpSi. I. 7. 8

sandhyā of 1,296,000/12; i. e. 108,000 years and at the close of tretā a sandhyāmsā of 108,000 years. Again, in the beginning of dvāpara we have a sandhyā of 864,000/12, i. e. 72,000 years and at the close of dvāpara a sandhyāmsā of 72,000 years; and similarly at the beginning a sandhyā and at the close a sandhyāmsā of 432,000/1, i. e. of 36,000 years in the case of kali. In this respect Brahmagupta appears to follow Manu, the first author or giver of law. He regards further the following divisions of time :¹

71 yugas = 1 manu

14 manus = 1 kalpa

Again, in the beginning, at the middle and at the close of each manu, there are sandhis, each equal to the measure of kṛta. Thus, taken as a whole

$$\begin{aligned} 1 \text{ kalpa} &= 71 \times 14 \text{ yugas} + 15 \text{ sandhyā-sandhyāmsā} \\ &= 994 \text{ yugas} + 15 \times \text{duration of kṛta} \\ &= 994 \text{ yugas} + 15 \times (4 \times 432,000) \text{ years} \\ &= 994 \text{ yugas} + 6 \text{ yugas} = 1000 \text{ yugas} \\ &= 1 \text{ Brahma-dina (Brahmā's day)} \end{aligned}$$

Thus Brahmā's day is regarded as 1 kalpa or one thousand caturyugis or 1000 *yugas* or the same as 1000 *mahāyugas*).

Āryabhata regards a manu to consist of 72 yugas and therefore a kalpa according to him would be of 14×72 yugas, or 1008 yugas.² Since in the foreign Siddhāntas like Romaka, there is no reference to yuga, manu and kalpa, Brahmagupta regards these systems to be unauthoritative.³

We have said that our starting point was the beginning of Kaliyuga. Friday February 18, B.C. 3102, at mean rise at Lankā, when the Sun, Moon and the planets are supposed to have been in conjunction at the first point of the Nakṣatra Aśvini. This type of conjunction would again happen after a period of *kalpa*.

3. कुम्भन्तरकल्पाः कालपरिच्छेदकाः स्मृतावुक्ताः ।

कल्पान्तरोपेक्षे ते स्मृतिबाह्ये रोमकस्तस्मात् ॥

—BrSpSi. I-13

We shall have the same type of conjunction of *grahocca*, *mandocca* *śighrocca* and *pāta* after a complete cycle of kalpa as we had in the beginning of creation. This is a natural observable cycle which is recognised in Indian astronomy and in no other foreign system; and hence only the Indian system recognises the time measure of *kalpa*.

Ucca or apex is of two kinds: *mandocca* (apex of the slowest motion) and *śighrocca* (apex of the fastest motion). The *mandocca* is that point of a planet's orbit which is at the remotest distance and where the motion of the planet is slowest. In the case of the Sun and the Moon, it is the apogee; and in the case of other planets, it is the apogee or aphelion, the geocentric longitude of the apogee being equal to the helio-centric longitude of the aphelion. The *śighrocca* of a superior planet (Mars, Jupiter and Saturn) is defined as the mean Sun; that of an inferior planet Mercury or Venus) *śighrocca* is an imaginary body which is supposed to move in such a way that its direction from the earth is always approximately the same as that of the actual planet from the Sun.

The *bhaganas* or the revolution numbers of a planet have been given by Āryabhaṭa and Brahmagupta¹ both; they mean the number of revolutions that a planet performs in a certain period, say a kalpa of 4,320,000,000 years.

The *bhaganas* of planets are given as follows :

1. कल्पेऽर्कबुधसितानां भगणाः शून्यानि सप्त रदवेदाः ।

Planet or a body	Bhagaṇas
Ravi or Sun	4,320,000,000
Budha or Mercury	4,320,000,000
Śukra or Venus	4,320,000,000
Candra or Moon	57,753,300,000
Kuja or Bhauma or Mars	2,296,828,522
Budha-śighrocca	17,936,998,984
Bṛhaspati or Jupiter	364,226,455
Śukra-śighrocca	7,022,389,492
Śani or Saturn	146,567,298
Arka or Ravi-mandocca	480
Candra mandocca	488,105,858
Kuja or Bhauma mandocca	292
Budha-mandocca	332
Bṛhaspati or Jīva-mandocca	855
Śukra-mandocca	653
Śani-mandocca	41
Candra-pāta	232,311,168
Kuja or Bhauma-pāta	267
Budha-pāta	521
Bṛhaspati or Guru-pāta	63
Śukra-pāta	893
Śani-pāta	584

By pāta is meant the ascending node of a planet's orbit (on the ecliptic).

In a kalpa, the number of *bha-bhramas* (sidereal days) or also known as *bha-parivartas* is 51,040,000,000. If we subtract out from this number the *bhagaṇa* of the Sun, we get what is known as *ku-dinas* or *Savana* days or the solar or sacrificial days. $(51,040,000,000 - 4,320,000,000 = 46,720,000,000)$ *Savana* days or *kudinas*).

In a kalpa, the number of Ravi-bhagaṇas also correspond to the number of solar years (*Saura-varṣas*). i.e., 4,320,000,000; this number multiplied by 12 gives the number (i.e. 51,840,000,000) of solar months.

The difference between the candra-bhagaṇas and the Ravi-bhagaṇas in a kalpa gives the number of lunar months (*Candra-*

māsa) in a kalpa (57,753,300,000-4,320,000,000=53,433,300,000 lunar months).

By subtracting the number of solar months from the number of lunar months in a kalpa, one gets the number of *adhi-māsa*s (additional-months) : 53,433,300,000-51,840,000,000=1,593,300,000 *adhimāsa*s. This multiplied by 30 gives the number of lunar days (śaśi-divasa) in a kalpa ; 53,433,300,000×30=1,602,999,000,000 lunar days. The difference between the lunar days and *kudinaś* in a kalpa gives the number of *avama-dina*s in a kalpa : 1,602,999,000,000-45,720,000,000=1,556,279,000,000.¹

Brahmagupta calculates out the *sr̥ṣṭi-samvatsara* or the Creation Era during his year of composition of the Treatise. He says : Six manus have gone in the kalpa ; the seventh manu is now running of which have lapsed 27 caturyugis ; of the twenty eighth caturyugī, the three yugas, *kṛta*, *dvāpara* and *tretā* have gone by and also of the present *kaliyuga* 3179 years have lapsed. The total period thus lapsed on calculation comes to be 1,972,947,179 years :²

$$\begin{aligned} \text{Total Period} &= 6 \text{ manus} + 7 \text{ manu} - \text{sandhis} + 27 \text{ yugas} \\ &+ \text{kṛta} + \text{dvāpara} + \text{tretā} + 3179 \text{ years of kali.} \\ &= (6 \times 71 \times 4,320,000 \text{ years}) + (7 \times 4 \times 432,000 \text{ years}) + \\ &(27 \times 4,320,000 \text{ years}) + (1,728,000 + 1,296,000 + 864,000) + \\ &3,179 = 1,972,947,179 \text{ years.} \\ &= 1,840,320,000 + 12,096,000 + 116,640,000 + 3,888,000 + \\ &3,179 = 1,972,947,179 \text{ years.} \end{aligned}$$

Calculation of Ahargana : The method of calculating *ahargana* (number of days elapsed since the beginning of *kaliyuga*)

BrSpSi. I. 26-27

has been given by Brahmagupta and Bhāskara I is almost identical. The rule given in the *Brahmasphuṭasiddhānta*¹ may be compared with the following given by Bhāskara I in the *Laghu-Bhāskarīya*:

Add 3179 to the (number elapsed) years of the Śaka era. (then) multiply (the resulting sum) by 12, and (then) add the (number of lunar) months (expired) since the commencement of Caitra. Set down (the result thus obtained) at (two) separate places; multiply (one) by (the number of) intercalary months in a *yuga*, which are 1,593,336 in a *yuga* : and divide (the product) by $5,184 \times 10,000$ (i.e.) by 51,840,000). Add the (resulting complete) intercalary months to the result placed at the other place. Then multiply (that sum) by 30 and (to the product) add the (lunar) days (i.e. *tithis*) expired of the current month. Set down (the result thus obtained) in two places; multiply (one) by the (number of) omitted lunar days in a *yuga* i.e. by 25,082,580 and divide by 1,603,000,080. The resulting (complete) omitted lunar days when subtracted from the result put at the other place give the (required) *ahargana*. The remainder obtained on dividing (the *ahargana*) by 7 gives the day beginning with Friday at sunrise (at Lāṅkā)²

— *LBh*. I. 4-8

Addendum : The mean lunar day (*madhyama tithi*) may, however, differ from a true lunar day (*spaṣṭa tithi*) by one, so that the *ahargana* obtained by the above process may sometimes be in excess or defect by one. To test whether the *ahargana* (obtained by the above process) is correct, it is divided by seven and the remainder counted with Friday. If this leads to the day of calculation, the *ahargana* is correct; if it leads to the preceding day, the *ahargana* is in defect; and if that leads to the succeeding day, the *ahargana* is in excess. When the *ahargana* is found to be in defect, it is increased by one; when it is found to be in excess, it is diminished by one. (K.S. Shukla : *MBh.* p. 4-5)

Example—Calculate the *ahargana* on October 1, 1965.

From Indian Calendar we find that October 1, 1965 falls on Friday. 7th lunar day (*tithi*) in the light half of the 7th month Āśvina in the Saka year 1887 (elapsed). Let us proceed as follows :

Adding 3,179 to 1,887. we get 5,066. (1)

Multiplying this by 12 and adding 6 (i. e. the number of lunar months elapsed since the beginning of Caitra) we get 60,798. ... (2)

Multiplying this by 1,593,336 and dividing the product by 51,840,000, we get 1,868 as quotient. (The remainder is discarded as unnecessary) (3)

Adding this number (i.e. 1,868) to the previous one (i.e. 60,798) we get 62,666. (4)

Multiplying this by 30 and adding 6 (i.e. the number of lunar days elapsed since the beginning of the current month) to the product, we get 1,879,986. (5)

Multiplying this by 25,082,580 and dividing the product by 1,603,000,080, we get 29,416 as the quotient. (The remainder is discarded as not necessary). (6)

Subtracting this number (i.e. 29,416) from the previous one (i.e. 1,879,986) we get 1,850,570. (7)

This is the required *ahargana*. Since division by 7 leaves

1 as the remainder. we subtract one from it, and get 1,850,569 as the correct *ahargana* for the day.

An Alternative Rule for *Ahargana*

Both Bhāskara I and Brahmagupta give an alternative rule for calculating out *ahargana*¹ :

Multiply the number of (solar months) elapsed since the beginning of kaliyuga by the number of lunar months (in a *yuga*) and divide by the number of solar months (in a *yuga*). Reduce the quotient to days (and add the number of lunar days elapsed since the beginning of the current lunar month); then multiply by the number of civil days (in a *yuga*) and divide by the number of lunar days (in a *yuga*); the quotient denotes the *ahargana*.

Mean Longitude of a Planet

(i) The mean longitude of a planet in *revolutions* is given by the expression : (Brahmagupta² and also Bhāskara³).

1. शशांकमासैरभिताडितान् हरेदतीतमासानर्थवार्कसम्भवे ।
दिनीकृतान् भूमिदिनैर्हृतान् दिनैर्विभज्य लब्धशशिशिजैरहर्गणः ॥ MBh. I. 7
युगगतशशिमासवधाद्रविमासाप्तं दिनीकृतं सदिनम् ।
भूदिनगुणितं शशिदिनहतमाप्तमहर्गणः सैकः ॥ —BrSpSi. XIII. 18
2. इष्टग्रह भगण गुणादहर्गणात् कल्पसावन च हुतात् ।
भगणादि फलं मध्यो लंकायां भास्करौदयिकः ॥ BrSpSi. I. 31
3. उदादितान् यान् भगणान् क्षमादिनैर्लभामहे कान् कलियातवासरैः ।
इति प्रलब्धा भगणास्ततः क्रमाद् गुहांशलिप्ता विकलाः सततपराः ॥ —MBh. I. 8
पर्ययाहर्गणाम्यासो ह्यिते भूदिनैस्ततः ।
लभ्य ते पर्ययाः शेषादांशि भागकलादयः ॥
भास्करैस्त्रिंशता षष्ठ्या सङ् गुणय्य पृथक् पृथक् ।
तेनैव भागहारेण लभ्यन्तेऽर्कोदयावधेः ॥ —LBh. I. 15-17

(Divide the product of the revolution-number of a planet and the *ahargana* by the (number of) civil days (in a *yuga*); thus are obtained the (number of) revolutions (performed by that planet). From the (successive remainders multiplied respectively by 12,30 and 60 and divided by the same divisor (i.e. the number of civil days in *yuga*) are obtained the signs, degrees and minutes etc. (of the mean longitude of that planet) for (mean) sunrise (at Lanka).

$$\text{Mean longitude} = \frac{\text{revolution number of planet} \times \text{ahargana}}{\text{civil days in a yuga}}$$

Similar expression is given by more recent Indian astronomers also.

(ii) Mean longitude of desired planets in minutes

$$\begin{aligned} & (\text{mean longitude of the known planet in revolutions etc. reduced to minutes}) \times (\text{revolution number} \\ & \quad \text{of the desired planet}) \\ & = \frac{\quad}{\text{revolution number of the known planet.}} \end{aligned}$$

This rule is common to Brahmagupta¹ and Bhāskara I².

(iii) An alternative rule for deriving the mean longitude of the Moon from that of the Sun and vice versa has been given by Bhāskara I and Brahmagupta both.

Multiply the *ahargana* by the number of intercalary months in a yuga and divide (the product) by the number of civil days (in a yuga): the result is in the terms of revolutions etc. Add that to thirteen times the mean longitude of the Sun. (This is the process) to obtain the mean longitude of the Moon³.

Mean longitude of the Moon

$$= \frac{(\text{intercalary months in a yuga}) \times \text{ahargana}}{\text{civil days in a yuga}} \text{ revolutions}$$

1. ज्ञातभगणादिभुक्तं सविकलमिष्टयुग भगणसंगुणितम् ।

ज्ञात युगभगणभक्तं मध्यो भगणादि फलमिष्टः ॥

—BrSpSi. XIII. 27

2. निशाकरं वाग्रहसुच्चमेव वा कर्लाकृतं तत्सह्युक्तमण्डलैः ।

यथेष्ट नक्षत्रगणैर्हृतं हरेत् तदीयनक्षत्र गणैस्ततः कला ॥

MBh. I. 10

The (mean) longitude of the Moon, the planet, or the *Ucca* (whichever is known) together with the revolutions performed should be reduced to minutes. The resulting minutes should then be multiplied by the revolution-number of the desired planet and (the product obtained should be) divided by the revolution-number of that (known) planet. The result is (the mean longitude of the desired planet) in minutes.

3. युगायां युगाधिसासैर्गुणितं युग भूदिनैर्भजेल्लब्धम् ।

भगणादि मध्यमाकं त्रयोदश गुणाधिकं चन्द्रः ॥

—BrSpSi. XIII. 33

युगाधिसासैर्गुणं हतं हरेत् क्षमादिनैर्वा भगणादि लभ्यते ।

त्रयोदशान्ने सवितर्यथा क्षिपेन्निशीथिनीनां पतिचारसिद्धये ॥

—MBh. I. 11

+13 (Sun's mean longitude)

This expression may be rearranged to get the mean longitude of the Sun from the mean longitude of the Moon¹.

Mean longitude of the Sun

$$= \frac{1}{13} [\text{mean longitude of the Moon} \\ - \frac{(\text{intercalary months in a } yuga) \times \text{ahargana}}{\text{civil days in a } yuga} \text{ revolutions}]$$

**Calculating the Mean
Longitudes of the Sun and
the Moon without using Ahargana**

Bhāskara I follows the method of Āryabhaṭa I and the same method more or less has been adopted by Brahmagupta in calculating the mean longitudes of the Moon and the Sun without the use of *ahargana*. The method may be described thus :

Reduce the years elapsed since the beginning of kali-yuga to months and add to them elapsed months of the current year. Then multiply the sum by 30 and add the product to the number of lunar days elapsed since the beginning of the current month. Multiply that sum by the number of intercalary months in a *yuga* and divide by the number of solar months in a *yuga* reduced to days; the quotient denotes the number of intercalary months elapsed. The remainder is the *adhimāsaśeṣa*. Multiply the complete intercalary months thus obtained by 30 and to the product add the number of solar days elapsed since the beginning of kaliyuga²; then multiply that sum by the number of omitted lunar days in a *yuga* and divide by the number of lunar days in a *yuga*; the remainder obtained is the *avamāśeṣa* called *āhnikā*. Then multiply the *avamāśeṣa*

1. कुसुमदीपां सुहृदोऽथवाऽऽगतं विरोधं शेषस्य लवस्त्रयोदशः ।

स मध्यमाको गणकैर्निरूप्यते गुरुप्रसादात्प्रति बुद्ध बुद्धिसिः ॥

MBh. I. 11-12

2. By the number of solar days here is meant the number obtained above by reducing the years elapsed since the beginning of kaliyuga to months, then adding to them the number of months elapsed since the beginning of the current year, then multiplying the sum by 30, and then adding to the product thus obtained the number of lunar days elapsed of the current month.

(also called *āhnika*) by the number of intercalary months in a *yuga* and divide by the number of civil days (in a *yuga*). Add the resulting quotient to the *adhimāsaśeṣa* and divide the sum by the number of lunar months in a *yuga* : this gives degrees etc. (This is the total *adhimāsaśeṣa*). Next multiply again the *avamaśeṣa* called *āhanika* by 60 and divide by the number of civil days in a *yuga* : the result is in minutes, seconds, thirds etc. The number of months elapsed (since the beginning of Caitra) are to be taken as signs and the number of lunar days elapsed of the current month as degrees. The sum of these signs and degrees and the minutes, seconds etc. corresponding to the *avamaśeṣa* is the *grahatanu*. From thirteen times and from one time that *grahatanu* severally subtract the degrees, minutes etc. corresponding to the total *adhimāsaśeṣa* : the remainders thus obtained are the mean longitudes of the Moon and the Sun respectively¹.

—MBh. I. 13-19

(Here verse 17 should follow verse 15—K.S. Shukla)

K. S. Shukla has provided the following rationale to the rule cited above :

The fraction of the intercalary month (obtained in the rule) = $\frac{\text{adhimāsaśeṣa}}{\text{solar days in a } yuga}$, in mean lunar months.

$$= \frac{\text{adhimāsaśeṣa}}{\text{lunar days in a } yuga}, \text{ in mean solar months. (i)}$$

The fraction of the omitted lunar day (obtained in the rule)

$$= \frac{\text{avamaśeṣa or āhnikā}}{\text{lunar days in a } yuga}, \text{ in mean civil days.}$$

$$= \frac{\text{avamaśeṣa}}{\text{civil days in a } yuga}, \text{ in mean lunar days.}$$

$$= \frac{\text{avamaśeṣa} \times 60}{\text{civil days in a } yuga}, \text{ in mean lunar } ghaṭis. \text{ (ii)}$$

The fraction of the intercalary month corresponding to the above fraction of the omitted lunar day

$$= \frac{(\text{intercalary months in a } yuga) \times (\text{avamaśeṣa})}{(\text{lunar days in a } yuga) \times (\text{civil days in a } yuga)},$$

in mean solar months. (iii)

Adding (i) and (iii) and multiplying by 30, the total fraction of the intercalary month

$$= \left\{ \frac{\text{adhimāsaśeṣa}}{\text{lunar months in a } yuga} + \frac{(\text{intercalary months in a } yuga) \times (\text{avamaśeṣa})}{(\text{lunar months in a } yuga) \times (\text{civil days in a } yuga)} \right\}$$

in mean solar days. (iv)

Suppose that m lunar months and d lunar days have elapsed since the beginning of Caitra. Then, treating them as mean lunar months and mean lunar days, m months and d days denote the time elapsed since the beginning of mean Caitra up to the beginning of the current lunar day (treated as mean lunar day). As (ii) is the interval, in mean lunar *ghaṭis*, between the beginning of the current lunar day and the mean sunrise on that day, therefore

$$m \text{ months} + d \text{ days} + (\text{ii})$$

denotes the time in mean lunar months, days, *ghaṭis*¹ elapsed

¹ 1 hour = 24 *ghaṭis*; 1 *ghaṭi* = 60 *vighaṭis*; 1 *vighaṭi* = 60 *pravighaṭis*.

since the beginning of mean Caitra up to the mean sunrise on the current lunar day.

Like wise

$$m \text{ months} + d \text{ days} + (ii) - (iv)$$

denotes the time in mean solar months, days, ghaṭis etc. elapsed since the beginning of the current mean solar year up to the mean sunrise on the current lunar day¹.

Let M, D, G, V, and P denote respectively the mean solar months, mean solar days, mean solar ghaṭis mean solar vighaṭis and mean solar pravighaṭis elapsed since the beginning of the current mean solar year up to the mean sunrise on the current lunar day. Then evidently mean longitude of the Sun

$$= M \text{ signs, } D \text{ degrees, } G \text{ minutes, } V \text{ seconds and } P \text{ thirds.}$$

$$= (m \text{ signs and } d \text{ degrees}) + [\text{minutes, seconds etc. corresponding to (ii)}] - [\text{degrees, minutes etc. corresponding to (iv)}].$$

and mean longitude of the Moon

$$= 13 [m \text{ signs and } d \text{ degrees} + (\text{minutes, seconds, etc. corresponding to (ii)}) - (\text{degrees, minutes etc. corresponding to (iv)})]$$

because

$$[(1/12) \text{ mean longitude of the Moon} - \text{mean longitude of the Sun.}]$$

$$= m \text{ signs} + d \text{ degrees} + (\text{minutes, seconds etc. corresponding to (ii)})$$

(This equality is based on the fact that the left hand side denotes the mean lunar date also known as *madhyama tithi*).

A similar rule of these calculations of the mean longitude

-
1. Because (iv) is equal to fraction of a lunar month between the beginning of Caitra and the beginning of the current mean solar year fraction of an intercalary month corresponding to the tithis elapsed up to the beginning of the current mean lunar day since the beginning of Caitra fraction of an intercalary month corresponding to the *avamaśeṣa*, i.e., the lunar portion between the beginning of the current lunar date and the following sunrise.

of the Sun and the Moon without basing on *ahargana* has also been given by Brahmagupta in the *Khaṇḍakhādya*¹.

Concordance of Working Rules

There has been a good deal of agreement on various rules of astronomical constants from the time of Āryabhaṭa I (499 A. D.) to the Bhāskara II (1150 A. D.) or even later to the days of Muniśvara (1620 A. D.). Earliest concepts were formulated during the days of the Vedāṅga-Jyautiṣa and the Siddhāntas of Indian and the western origin, for example of Brahma, Vasiṣṭha, Pitāmaha, Romaka and Pulīśa. We in this section are giving some important concordances which we find common in the writings of Brahmagupta and his predecessors, contemporaries and successors as listed below. The list is not exhaustive. Only a few illustrations have been cited.

1. Ārya.—*Āryabhaṭīya*, Āryabhaṭa I, 499 A. D.
2. BrSpSi.—*Brahmasphuṭasiddhānta*, Brahmagupta, 628 A. D.
3. K. K.—*Khaṇḍakhādya*, Brahmagupta, 628 A. D.
4. KKu.—*Karṇa-kutūhala*, Bhāskara II, 1150 A. D.
5. LBh.—*Laghu-Bhāskariya*, Bhāskara I, 522 A. D.
- MBh.—*Mahā-Bhāskariya*, Bhāskara I, 522 A. D.
- MSi.—*Mahā-siddhānta*, Āryabhaṭa II, 950 A. D.
- PSi.—*Pañcasiddhāntikā*, Varāhamihira, 505 A. D.
- ŚiDVṛ.—*Śiṣyadhivṛddhida*, Lalla, 598 A. D.
- SiSā.—*Siddhāntasārvabhauma*, Muniśvara, 1620 A. D.
- SiSe.—*Siddhāntasekhara*, Śripati, 1039 A. D.
- SiŚi.—*Siddhānta-Śiromaṇi*, Bhāskara II, 1150 A. D.
- SuSi.—*Sūryasiddhānta*, Modern, 6th or 7th Century.

12. For finding the times of rising of the sāyana signs at the equator : *BrSpSi*. III. 15.

Also *MBh*. III. 9 ; *SuSi*. III. 42-43 : *ŚiDVṛ*. I. iii. 8 ; *SiŚe*. IV. 15 ; *SiŚi* I. 11. 51.

13. Rule for finding the ascensional differences of the Sāyana signs Aries, Taurus and Gemini : *KK*. 1. 21.

Also *MBh*. III. 8 ; *PSi*. III. 10 ; *ŚiDVṛ*. 1. XIII. 9 ; *SiŚi*. I. ii. 50-51.

14. Rule for the determination of the meridian zenith distance and meridian altitude of the Sun with the help of the Sun's declination and the latitude of the place ; *BrSpSi*. III. 47.

Also *MBh*. III. 11 ; *LBh*. III. 27 ; *ŚiDVṛ*. I. iii. 16 ; *SiŚe*. IV. 42.

15. Rule for determination of the latitude with the help of the Sun's meridian zenith distance and declination ;

BrSpSi. : III. 13.

Also *MBh*. III. 17; *LBh*. III. 34; *SuSi*. III. 15-16; *SiŚe*. IV. 51,

16. Rule for finding out the Rsine of the Sun's altitude for the given time in *ghaṭas* : *BrSpSi*. III. 25-26 Also *Ārya* IV. 28; *MBh*. III. 18-20; *LBh*. III. 7-10; *ŚiDVṛ*. I. iii. 24-25; *SiŚe*. IV. 32,34; *SiŚi*. I. iii. 53-54.

17. Rule for finding out the Sun's altitude : $R \sin \alpha =$

$$\frac{M \times \text{day radius}}{R} \times \frac{\text{gnomon}}{\text{hypotenuse of equinoctial midday shadow}}$$

where $M = R \sin (\text{given } ghaṭas \mp \text{asc. diff.}) R \sin (\text{asc. diff.})$, the upper or lower sign being taken according as the Sun is the northern or southern hemisphere, α is the Sun's altitude. *BrSpSi*. III. 27 (i).

Also *MBh.* III 24; *ŚiDVṛ.* I. iii. 27; *SiŚe* IV. 37

18. Rule for finding the Sun's altitude when the Sun's ascensional difference is greater than the given time : *BrSpSi.* III. 33 :

Also *MBh.* III 25, *LBh.* III. 11; *ŚiDVṛ.* I. iii. 29 *SiŚe.* IV. 41.

19. Rule for finding the Sun's altitude in the night : *BrSpSi.* III. 63.

Also *MBh.* III. 26; *LBh.* III. 11; *SiŚe.* IV. 89.

The Sun's altitude for the night has been called *Patāla Śanku* by Brahmagupta (*BrSpSi.* XV.9)

20. Rule for finding the longitude of the rising point of the ecliptic with the help of (i) the instantaneous sāyana longitude of the Sun and (ii) the civil time measured since sunrise, or with the help of (i) the Sun's sāyana longitude at sunrise and (ii) the sidereal time elapsed since sunrise : *BrSpSi* III. 18-20.

Also *MBh.* III. 30-32; *LBh.* III. 17-19; *SūSi.* III. 46-48;

ŚiDVṛ. I. iii. 11-12; *SiŚe* IV. 18-19 (i) : *SiŚi* I. iii. 2-4.

21. Rule for obtaining the civil time measured since sunrise with the help of (i) the Sun's instantaneous sāyana longitude and (ii) the sāyana longitude of the rising point of the ecliptic, or the sidereal time elapsed since sunrise with the help of (i) the Sun's sāyana longitude at sunrise and (ii) the sāyana longitude of the rising point of the ecliptic : *BrSpSi* III. 21-23.

Also *SūSi.* III.50-51; *MBh.* III. 34-36; *LBh.* III. 20;

ŚiDVṛ. I. iii. 13; *SiŚe* IV. 19 (ii)—22 (i); *SiŚi* I. iii. 5-7. (i).

22. Rule for determining the R Sines of the Sun's prime vertical altitude : *BrSpSi* III. 52.

Also *Ārya.* IV; *MBh.* III.37-38; *LBh.* III. 52.

(An error created by Āryabhata has been criticised by Brahmagupta.)

23. Construction of the locus of the end of the shadow of a gnomon : *BrSpSi.* III. 2-3.

Also *MBh.* III 52; *ŚiDVṛ.* I. iii. 3; *SiŚe.* IV. 5;

24. Rule for finding the Sun's mean anomaly : *BrSpSi.* II. 12 (i).

Also *MBh.* IV. 1; *SuSi.* II. 29; *ŚiDVṛ.* I. ii. 10; *SiŚe.* iii. 12; *SiŚi.* I. ii. 18-19 (i).

25. Rule for finding the RSine (Reversed sine) of an arc ($<90^\circ$): *BrSpSi.* II. 10.

Also *SuSi.* II. 31-32; *MBh.* IV. 3-14; *LBh.* II, 2 (11)-3 (i); *ŚiDVṛ.* I. ii. 12; *SiŚe.* III. 15; *SiŚi.* I. ii. 10 (ii)-11.

(We shall discuss it separately in the light of Brahmagupta formula.)

26. Rule for finding the Sun's equation of the centre: *BrSpSi.* II. 15 (ii);

Also *MBh.* IV. 4 (ii); . III *SiŚe.* 27

27. Rule for determining the Sun's true longitude: *BrSpSi.* XIV. 17-18.

Also *MBh.* IV. 21-23; *SiŚe.* III. 52.

28. Rule for finding the Sun's *bhujāntara* correction under the eccentric theory : *BrSpSi.* XIV. 19.

Also *MBh.* IV. 24.

29. Rule for determining the *cara-saṃskāra* or *cara* correction : *KK.* I. 22.

30. Rule for finding the semi-durations of the day and night : *BrSpSi.* II. 60; *KK.* I. 23.

Also *SuSi.* II. 62-63; *ŚiDVṛ.* I. ii. 20-21; *SiŚe.* III. 70; *SiŚi.* I. ii. 52.

31. Rule for calculating the *tithi* : *BrSpSi.* II. 62; *KK.* I. 25.

Also *SuSi.* II. 66; *ŚiDVṛ.* I. ii. 22; *SiŚe.* III. 71; *SiŚi.* I. ii. 66.

32. Rule for calculating the *Karāṇa* : *KK.* I. 27.

Also. *ŚiDVṛ.* I. ii. 24; *SiŚe.* III. 77; *SiŚi.* I. ii. 66.

33. Rule for calculating *nakṣatra* : *BrSpSi.* II. 62; *KK.* I. 24.

Also *SuSi.* II. 64; *ŚiDVṛ.* I. ii. 23 (i); *SiŚe.* III. 75; *SiŚi.* I. ii. 67.

34. Rule pertaining to direct and retrograde motions of a planet : *BrSpSi.* II. 50-51.

Also *MBh.* IV. 56-57 ; *SiŚe.* III. 59 ; *ŚiDVṛ.* I. ii. 42 ;

35. A rule for converting true distances known in minutes into true distances into *yojanas* : for example : Sun's true distance in *yojanas*

$$\frac{\text{Sun's mean distance in } yojanas \times \text{Sun's true dist. in minutes}}{\text{Radius}}$$

BrSpSi. XXI. 31 (ii).

Also *MBh.* V. 3 ; *ŚiDVṛ.* I. iv. 5 (i) ; *LBh.* IV. 3 ; *SiŚe.* V. 4 (ii) ; *SiŚi.* I. v. 5 (i) ;

36. Rule for finding angular diameters of the Sun and the Moon : *BrSpSi.* XXI. 34 (ii) ;

Also *MBh.* V. 5 : *ŚiDVṛ.* I. iv. 8 ; *SiŚe.* V. 6 ; *SiŚi.* I. v. 7,

37. Formulae for the true (i. e. angular) diameters of the Sun, the Moon and the shadow in terms of the true daily motions of the Sun and the Moon (Here by shadow is meant the section of the cone of the Earth's shadow at the Moon's distance.) : *BrSpSi.* IV. 6 (i) ; *KK.* IV. 2 (i).

Also *MBh.* V. 6-7 ; *ŚiDVṛ.* I. iv. 9 ; *MSi.* V. 5 (ii) ;

SiŚe. V. 9 ; *SiŚi.* I. v. 8-9 ;

38. Rule for finding the *spaṣṭa-valana* (resultant *valana*) for the circle drawn with half the sum of the diameters of the eclipsed and eclipsing bodies as radius : *ErSpS.* IV. 18 (i).

Also *MBh.* V. 46 ; *ŚiDVṛ.* I. iv. 26.

39. Method for calculating the phase of the eclipse for the given time : *BrSpSi.* IV. 11-12.

Also *MBh.* V. 62-63 ; *ŚiDVṛ.* I. iv. 19-20 ; *SiŚe.* V. 14.

40. Rule for the determination of the diameter of the shadow i.e., the diameter of the Section of the Earth's shadow where the Moon crosses it : *BrSpSi.* XXIII. 8-9.

Also *MBh.* V. 71-73 ; *Ārya.* IV. 39-40 ; *ŚiDVṛ.* I. iv. 6 (ii)-7.

41. Process of successive approximations in connection with calculations of a lunar eclipse : *BrSpSi.* IV. 8-9.

Also *MBh.* V. 75-76 ; *LBh.* IV. 10-12 ; *ŚiDVṛ.* I. iv. 14-16 ; *SiŚe.* V. 12-13 ; *SiŚi.* I. v. 12-13.

42. Rule relating to the visibility-correction known as *akṣa-dṛkkarma* : *BrSpSi*. VI. 4.

Also *MBh*. VI. 1-2; *ŚiDVṛ*. I. vii. 3 (ii); *MSi*. VII. 4; *SiŚe*. IX. 7.

43. Rule relating to the visibility correction known as *ayanadṛkkarma* : *BrSpSi*. VI. 3; X. 17.

Slightly modified in *MBh*. VI. 2 (ii)-3; *ŚiDVṛ*. I. vii. 2-3 (i) · *SiŚe*. IX. 4-5; similar in *MSi*. VII. 2-3; more accurate in *SiŚi*. I. viii. 4-5.

44. Rule relating to the visibility of moon : *BrSpSi*. VI. 6; X. 32.

Also *MBh*. VI. 4-5 (i) *PSi*. V. 3; *ŚiDVṛ*. I. vii. 5; *SiŚe*. IX. 8 (i). 13.

45. Rule for calculating the phase of the Moon : *BrSpSi*. VII. 11 (ii)-12.

Also *MBh*. VI. 5 (ii)-7; *ŚiDVṛ*. I. ix. 12.

46. Rule for the determination of the Moon's true declination (i.e. the declination of the centre of the Moon's disc) : *BrSpSi*. VII. 5.

Also *MBh*. VI. 8; *ŚiDVṛ*. I. viii. 2; *SiŚe*. X. 7. (these are approximate rules; a more accurate rule occurs in *SiŚi*. I. vii. 3 and 13).

47. Graphical representation of the elevation of the lunar horns in the first quarter of the month at sunset : *BrSpSi*. VII. 7-10.

Also *MBh*. VI. 13-17; *ŚiDVṛ*. I. ix; *SiŚi*. I. ix.

48. Minimum distances of the planets from the Sun when they are visible : *BrSpSi*. vi 6; X. 32.

Also *MBh*. VI. 44; *ŚiDVṛ*. I. vii. 5 (i); *SiŚe*. IX. 8 (i). 12.

49. Rule relating to the determination of the time and the common longitude of two planets when they are in conjunction in longitude : *BrSpSi*. IX. 5-6.

Also *MBh*. VI. 49-51; *ŚiDVṛ*. I. x. 7-9 (i); *SiŚe*. XI. 12-12.

50. Rule relating to the distance between two planets

which are in conjunction in longitude : *BrSpSi*. IX. 11.

Also *MBh*. VI. 54 ; *ŚiDVṛ*. I. x. 11 ; *SiŚe*. XI. 10.

51. Rule For finding the *Bhujaphala* and *Koṭiphala* etc. without the use of the RSine-difference table : *BrSpSi*. XIV. 23-24.

Also *MBh*. VII. 17-19 ; *SiŚe*. III. 17.

52. To obtain the Sun's mean true longitude derived from the midday shadow of the gnomon : *BrSpSi*. XIV. 28; III. 61-62.

Also *MBh*. VIII. 5; *SiŚi* I. ii. 45.

53. Rule to find the arc corresponding to a given RSine : *BrSpSi* II. 11.

Also *MBh*. VIII. 6; *SūSi*. II. 33, *ŚiDVṛ*. I. ii. 13, *SiŚe*. III. 16, *SiŚi*. I. ii. 11 (ii)—12 (i).

For the concordance given here we express our indebtedness to the work of K.S. Shukla on the *Mahābhāskariya*.

Tables of Constants

Some of the Tables of Constants have been given in an earlier chapter. We here give a few more tables which would indicate how far Brahmagupta introduced new concepts in evaluating these constants of greater accuracy and refinement.

TABLE I

Position of Planets for the Beginning of *kaliyuga*

In this Table are given the positions of the planets, including the Moon's apogee and ascending node, for the beginning of *Kaliyuga*. The calculations of Brahmagupta are different from those of the *Sūryasiddhānta* and of Āryabhaṭa I,

Planet	Positions <i>BrSpSi</i> .	according <i>Ārya</i> .	to <i>SūSi</i>
1	2	3	4
Sun	^s 0 0 0 0	^s 0 0 0 0	^s 0 0 0 0
Moon	0 0 0 0	0 0 0 0	0 0 0 0

1	2	3	4
	s°'''	s°'''	s°'''

backing to the west) in one day. It is sufficient to postulate the existence of only one Sun, one Moon and twenty-seven nakṣatras to explain the astronomical phenomena.¹

3. Brahmagupta differs from Āryabhaṭa I in the length of the four *yugas*. Āryabhaṭa regards all the four *yugas* of equal lengths, i. e. 1,080,000 years; the *caturyuga* being of 4,320,000 years. Brahmagupta regards *Kaliyuga* to be of 432,000 years, *Dvāpara* to be twice of it, *Tretā* to be thrice of it and *Kṛtayuga* of four times of the length of the *Kaliyuga*. Both have the *caturyuga* of the same length.²

4. Āryabhaṭa was not clear with respect to the number of civil days (*sāvana dina*) in a *yuga*; in one of his treatises he gives this number to be 1,577,917,800 and in the other 1,577,917,500 with a difference of 300 days, though in both the treatises, Āryabhaṭa I regards the number of solar years to be 4,320,000 in a *Caturyuga* or *Mahāyuga*. Why is this difference? asks Brahmagupta.³

5. Āryabhaṭa regards *mandocca* (the apogee) and *pāta* (the ascending node of the orbit on the ecliptic) as constant or stationary; then how could he propound a *sphuṭa-yuga* or the concept of true *yuga* with the concurrence of year, month and day on the Caitra Śukla Pratipadā (the first day of bright half of the month Caitra) at the same time as indicated by Āryabhaṭa in his *Laghvāryabhaṭīya Tantra*.⁴

Āryabhaṭa was not clear in respect to the variance in the *pāta*. In the *Āryaṣṭa-śata* (in the *Āryabhaṭīya* which has 108 Ārya verses), Āryabhaṭa states that the *pāta* of all the planets

1. मनिचतुस्फुचाराद्द्वौ द्वावकैः द्वावौ विनोक्तं यत् ।

show variance of movement, but in the *Daśagītikā* (a chapter of ten *Āryā* verses), he states that with the exception of the *pāta* of the *Moon*, the *pāta*'s of all other planets are stationary or constant. Brahmagupta points out this anomaly in the concept of *Āryabhata*.¹

6. Brahmagupta points out a self-contradiction in *Āryabhata*. At one place he says that the Moon covers the Sun during the solar eclipse and similarly the shadow of the Earth covers the Moon during the lunar eclipse (and he does not mention *Rāhu*) in this connection (*Āryabhaṭīya*, Gola. 37). At the same time it is said that *Āryabhata* was familiar with the movement of "eight" planets, and thus postulating the presence of *Rāhu*; in fact, the *pātas* of planets are responsible for their eclipse, and the eighth planet *Rāhu* is not present.²

7. *Āryabhata* gives measures to Manus, Yugas and Kalpas different from what have been given in the recognised *Smṛtis*.³

8. *Āryabhata* regards *Guruvāra* or Thursday to be the first day of the *Kalpa*, and not Sunday, which is wrong according to Brahmagupta.⁴

9. Brahmagupta unnecessarily criticises *Āryabhata* in respect to the order of days. The motion of the planets decreases in the following order : Moon, *Budha* (Mercury), *Sukra* (Venus), Sun, *Kuja* (Mars), *Guru* (Jupiter) and *Śani* (Saturn). *Āryabhata* in one of his verses states that starting from the Sun and proceeding in the increasing order every fourth is the *dinapati* or the "lord of the day" (*Āryabhaṭīya*, Kāla. 16) ; this gives the order : Sun, Moon, Mars, Mercury, Venus and Saturn and hence the order of days as *Ravivāra* (Sunday); *Candravāra* (Monday);

1. आर्याष्टशते पाता भ्रमन्ति दशगीतिके स्थिराः पाताः ।

मुत्तवेन्दु पातमपमण्डले भ्रमन्ति स्थिरा नातः ॥

—*BrSpSi*. XI. 11

Mangalavāra (Tuesday), (*Budhavāra*) (Wednesday), *Guruvāra* (Thursday) *Sukravāra* (Friday) and *Śanivāra* (Saturday). Thus Āryabhaṭa gives the same order of days as other authorities and there is no reason why he should be criticised.

Certainly what is Sunday for Lāṅkā, may not be Sunday at the same time for Siddhapura; and Āryabhaṭa should have emphasised that the day (Monday, Tuesday etc.) is not constant for all the places.¹

10. Brahmagupta expresses surprise why Āryabhaṭa, in two of his treatises propounds two different systems of reckoning one from the Sunrise in Lāṅkā and the other from the Midnight in Lāṅkā.² This causes a difference of one-fourth of the daily-motion in the two reckonings of the motion of planets.³

11. Brahmagupta criticises Āryabhaṭa on the point of diameter of the Earth. In the *Gatikāpāda*, 5 and 6, Āryabhaṭa states that one *yojana*=8,000 × *puruṣa*, and 1 *puruṣa*=4 *hasta*, thus 1 *yojana*=32,000 *puruṣas*, and the diameter of the Earth is 1050 *yojanas*. Brahmagupta further says that an error in the diameter of the Earth would cause an error in *deśāntara* or longitude and thus also in the true *ṭīthi* and consequently in the calculation of eclipses also.⁴

12. Āryabhaṭa has rightly stated that the Earth is in motion and the *Bhaganas* are stationary. Brahmagupta's objection is that if the Earth is in motion, birds would not be able to return to their nests, and if the Earth's motion is upside-down,

—BrSpSi. XI. 15-16

then the roof and hills would come down, which is contrary to our observation.¹ Obviously Brahmagupta is not justified in his criticism.

13. Brahmagupta points out to the differences in his calculations and the calculations of Āryabhaṭa in the peripheries of the *manda* and *śighra* epicycles of planets in the odd and even quadrants. (This difference we have shown in Table V, p. 313)²

14. Āryabhaṭa I and Bhāskara I have both given a rule for the determination of the *ḍṛkkṣepajyā*s of the Sun and the Moon :

Take the product of the Sun's or Moon's own *madhyajyā* and *udayajyā*, then divide the product by the radius and then take the square of the quotient. Subtract that from the square of the own *madhyajyā*; the square-root of that difference is known as the Sun's or Moon's *ḍṛkkṣepajyā*.³

The Sun's *ḍṛkkṣepajyā* is the Rsine of the zenith distance of that point of the ecliptic which is at the shortest distance from the zenith (this point is called nonagesimal or the central ecliptic point). The Moon's *ḍṛkkṣepajyā* is the Rsine of the zenith distance of that point of the Moon's orbit which is at the shortest distance from the zenith. The rule given above is only approximate and has been criticised by Brahmagupta.⁴

15. In the *Āryabhaṭīya*, there is a rule in the Golapāda for finding the Rsine of the *agra* of the true Sun; and also for the

1. प्राग्येनेति कलां भूर्यदि तर्हि कुतो ब्रजेत् कमध्वानम् ।

—*BrSpSi*. XI. 29-30

Rsine of the Sun's prime vertical altitude.¹ Bhāskara also gives the rule in his *Mahābhāskariya* :

Multiply the Rsine of the (Sun's) greatest declination by the Rsine of the Sun's true (*śayana*) longitude; then divide (the product) by the Rsine of the colatitude, the result is (the Rsine of) the *agra* of the true Sun. When that (*agra*) is less than the latitude and when the Sun is also in the northern hemisphere, multiply (the Rsine of the Sun's *agra*) by (the Rsine of) the colatitude; the result is the Rsine of the Sun's prime vertical altitude.²

The condition laid down in the rule that the "Sun's *agra* should be less than the latitude" is incorrect. The error was originally committed by Āryabhaṭa and Bhāskara followed it. This error was noticed by Brahmagupta³. Bhāskara I, however, corrected the error in the *Laghu-Bhāskariya*. There he gives the correct conditions. It is not the *agra* that should be less than the latitude, it is the Sun's declination (or rather the Rsine of the Sun's northern declination as we have in the *Laghu-Bhāskariya*), which should be less than the latitude (or rather the Rsine of the latitude). This condition is necessary for the existence of the prime vertical shadow of the gnomon.

It may be pointed out that the commentators of Āryabhaṭa I have interpreted the rule given by Āryabhaṭa I as conveying the correct meaning; they say that Āryabhaṭa also meant declination when he used the term *agra*.

1. परमापक्रमजीवामिष्टव्यार्थाहतां ततो विभजेत् ।

—BrSpSi. XI. 22

Usually by *agra*, we mean the arc of the celestial horizon lying between the east point and the point where a heavenly body rises; or between the west point and the point where a heavenly body sets. Declination is *krānti*.

16. Brahmagupta has criticised Āryabhaṭa and his group for their expressions for determining *lambana* (i. e. the difference of the parallaxes, in longitude, of the Sun and the Moon), and the rule for determining the *avanati* or *nati* (i.e. the difference in parallaxes, in latitude of the Sun and Moon).¹

Lambana is obtained with the help of the five Rsines : (i) *madhya-jyā*, (ii) *udaya-jyā*, (iii) *ḍṛk-kṣepa-jyā*, (iv) *ḍṛg-jyā*, and (v) *ḍṛg-gati-jyā*.

(i) The *madhyajyā* is the Rsine of the zenith distance of meridian ecliptic point :

madhyajyā = $R \sin (\phi \pm \text{declination of the meridian ecliptic point})$.²

In this expression ϕ is the latitude of the place, and by $R \sin$ is meant $R \times \text{sine}$, R being the radius of the celestial sphere.

(ii) The *udayajyā* is the Rsine of the arc of the horizon intervening between the equator and the ecliptic, and is given by :

$$\text{udayajyā} = \frac{R \sin L \times R \sin e}{R \cos \phi}$$

where L is the longitude of the horizon ecliptic point in the east, and e the obliquity of the ecliptic.

(iii) The *ḍṛkksepajyā* is the R sine of the zenith distance of the central ecliptic point³, and is given by :

1. व्यासार्धेन विभक्ता दृग्गति जीवा चतुर्गुणा लब्धम् ।

लम्बननाडयः पञ्चदशगुणितया त्रिज्यया भक्ता ॥

दृक्क्षेपज्या भुक्तयन्तराहता लब्धमवनतिर्भवति ।

आर्यभटेनास्मिन् सति लघुनि विमर्थं महत् कृतं कर्म ।

गणिता ब्रह्माज्जाड्यं विज्ञानता यदि ततः सुतराम् ॥

—BrSpSi. XI. 23-25

2. The meridian ecliptic point is the point of the ecliptic on the meridian.

3. The central ecliptic point is the central point of the portion of the ecliptic lying above the horizon.

$dṛkkṣepajyā$

$$= \left[(madhyajyā)^2 - \left\{ \frac{udayajyā \times madhyajyā}{R} \right\}^2 \right]^{\frac{1}{2}}$$

where R is the radius of the celestial sphere.

(iv) The $dṛgjyā$ is the Rsine of the zenith distance (of the Sun) and is given by :

$$dṛgjyā = \left[R^2 - \left\{ \frac{dṛggatijyā \times R \sin(L - \theta)}{R} \right\}^2 \right]^{\frac{1}{2}}$$

where L is the longitude of the horizon ecliptic in the east and θ the longitude of the Sun.

(v) The $dṛggatijyā$ is the Rsine of the altitude of the central ecliptic point, and is given by :

$$dṛggatijyā = [R^2 - (dṛkkṣepajyā)^2]^{\frac{1}{2}}$$

where R is the radius of the celestial sphere.

In the *Mahābhāskarīya*¹, the expression for the Sun's $dṛggatijyā$ is :

$$\begin{aligned} & (\text{Sun's } dṛggatijyā)^2 \\ &= (\text{Sun's } dṛgjyā)^2 - (\text{Sun's } dṛkkṣepajyā)^2 \end{aligned}$$

and similar is the expression for the the Moon's $dṛggatijyā$.

Now *lambana*, which is the difference of the parallaxes, in longitude, of the Sun and the Moon, is given by the expression :

$$Lambana = \text{Moon's } lambana - \text{Sun's } lambana.$$

Sun's *lambana*

$$= \frac{\text{Sun's } dṛggatijyā \times \text{Earth's semidiameter}}{\text{Sun's true distance in } yojanas}$$

Moon's *lambana*

$$= \frac{\text{Moon's } dṛggatijyā \times \text{Earth's semi-diameter}}{\text{Moon's true distance in } yojanas}$$

These *lambanas* are in terms of minutes of arc etc².

1. स्वहृदये ष शुषयोर्वर्गं विरलेषजे पदे ।

हृदयत्विजे भवेतां ते भास्करामृत तेजसः ॥

—MBh. V, 23

2. स्वहृदयेष्वमा व्यास मेद संवर्गं संभवम् ।

हृदयोक्तं कर्त्तव्यं लिप्तायं लम्बनं किदुः ॥

Thus *lambana* is given by subtracting the Sun's *lambana* from Moon's *lambana*.

This *lambana* is also expressed in the following way .

Lambana

$$= \left[\frac{\{(drgiyā)^2 - (drkkṣepajyā)^2\}^{1/2} \times 18}{\text{Moon's true distance}} - \frac{\{(drgiyā)^2 - (drkkṣepajyā)^2\}^{1/2} \times 18}{\text{Sun's true distance}} \right] \text{ in minutes.}$$

$= \frac{60}{d} \times (\text{lambana calculated in minutes})$ is the *lambana* in *ghaṭis*, where *d* denotes the difference between the daily motions of the Sun and the Moon.

Aryabhaṭa I has given his description of the determination of *lambana* and *avanati* in the Golapāda 33, 34 of the *Āryabhaṭīya*¹, and Bhāskara has followed his rules in the *Mahābhāskarīya*². Brahmagupta criticises them in his *Brāhma-sphuṭasiddhānta*³.

(vii) We shall now take up *nati* or *avanati* (both the terms mean the same). *Nati* is the difference of the parallaxes in latitude, of the Sun and the Moon and is given by :

$$\text{nati} = \left[\frac{drkkṣepajyā \times 18}{\text{Moon's true dist.}} - \frac{drkkṣepajyā \times 18}{\text{Sun's true dist.}} \right] \text{ minutes.}$$

2. loc. cit. MBh. V. 24-27

3. loc. cit. BrSpSi. XI. 23-25

(viii) Moon's true latitude = Moon's latitude \times *nati*.

The present *Sūryasiddhānta* and *Brahmagupta* both utilise the following expressions for *lambana* and *nati* which give more accurate values :

$$lambana = \frac{R \sin (M - \odot) \times drgatiyā}{\{R \sin (30^\circ)\}^2} \text{ ghaṭis}$$

where *M* and \odot denote the longitudes of the meridian ecliptic and the Sun respectively.

$$nati = \frac{drkṣepajyā \times d}{15 \times R}$$

where *R* is the radius of the celestial sphere and *d* denotes the difference between the daily motions of the Sun and the Moon¹.

Brahmagupta has raised objections to the *Āryabhaṭa* system regarding *lambana* (XI. 26-28), *drkṣepa* (XI. 30-31) *ayanadrk-karma* (XI. 35), elevation of Moon's horns (*śṛṅgonnati*) (XI. 39) and similar several other points. He is so vehemently opposed to *Āryabhaṭa* that finally he declares :

"It is beyond my capacity to enumerate all the defects of *Āryabhaṭa*. Only a few have been given here as illustration. Intelligent people can easily find out others².

He also says :

Āryabhaṭa is neither conversant with the *Gaṇita* (mathematics), nor *Kāla* (time calculations) nor *Gola* (celestial or spherical calculations). It is difficult to enumerate separately the fallacies committed by him in the respective chapters of the *Gaṇitapāda*, *Kālakriyapāda* and *Golapāda*³.

Brahmagupta and Śrīṣeṇa

In Varāhamihira's *Pancasiddhāntikā* we have a critical review of the five *Siddhāntas* or five systems of astronomical study : Puliśa Siddhānta, Romaka Siddhānta, Vasiṣṭha Siddhānta, Sūrya Siddhānta and Brāhma Siddhānta. Colebrooke in his Paper "On the notion of the Hindu Astronomers concerning the precession of the equinoxes and motions of the planets", published in the *Asiatic Researches*, vol. xii. p. 209-250, Calcutta. 1816,4 to, reproduced in the *Miscellaneous Essays*. Vol. II. 1872, says the following in regards to the authorship of these schools of astronomy :

All these books are frequently cited in the astronomical compilations and are occasionally referred to their real or supposed authors. The first is everywhere assigned to Puliśa, whose name it bears. The *Romaka Siddhānta* is ascribed by the scholiast of Brahmagupta and by a commentator of the *Sūrya Siddhānta* to Śrīṣeṇa. The *Vāsiṣṭha Siddhānta* is by the same authority given to Viṣṇucandra. Both these authors are repeatedly mentioned with censure by Brahmagupta ; and it is acknowledged that they are entitled to no particular deference.

The *Brāhmṇa Siddhānta*, which is the basis of Brahmagupta's work, is not anywhere attributed to a known author ; but referred to in all quotations of it which have fallen under observation, either to the *Viṣṇudharmottara Purāṇa*, of which it is considered as forming a part, or to Brahmā (also called Pitāmaha) who is introduced into it as the speaker in a dialogue with Bhṛgu, or it is acknowledged to be the work of some unknown person. The true author it may be now impracticable to discover, and would be vain to conjecture.

The *Sūrya Siddhānta* (if the same which we now possess) is in the like manner ascribed to no certain author unless in the passage cited by my colleague Mr. Bently (*Asiatic Researches*, vol. vi. p. 572) who says that "in the commentary of the *Bhāsvatī* it is declared, that

Varāha was the author of the *Sūrya Siddhānta*’, and who adds, that “Satānanda, the author of the *Bhāsvatī* was a pupil of Varāha under whose directions, he himself acknowledges, he wrote that work”.

This concluding remark alludes to the following verse of the *Bhāsvatī Karāṇa* : “Next I will propound succinctly, from Mihira’s instruction, (the system) equal to the *Sūrya Siddhānta*’, (*Miscellaneous Essays*, p. 388-90) (The word ‘Mihira’ has double meaning : it might be an abbreviation of *Varāhamihira*, or it may mean sun or *Sūrya*).

Thus on the authority of Colebrooke, Śrīṣeṇa may be regarded as the initiator of the Romaka system. Brahmagupta himself mentions in one of his passages the name of Śrīṣeṇa in connection with the Romaka system, and further the conceptions of the Romaka system came down as Vāsiṣṭha system through Viṣṇucandra,² Lāṭadeva also derived from Śrīṣeṇa the concepts of the mean motions of the Sun, the Moon, the Moon’s apogee and her node and the mean motions of Mars, Mercury’s, *Śighra*, Jupiter, Venus’ *śighra* and Saturn. I have indicated elsewhere, which is also the view of Sankara Bālakṛṣṇa Dikṣita, that the original Romaka and Pauliśa Siddhāntas were introduced to Indians by Lāṭadeva, and the latter Romaka Siddhānta by Śrīṣeṇa (Original Romaka Siddhānta was prevalent before Śaka 427 and this is the one which is mentioned by Varāhamihira who makes no reference to Śrīṣeṇa and Viṣṇucandra in the *Pañcasiddhāntikā*, and the latter Romaka Siddhānta was introduced by Śrīṣeṇa as is indicated by Brahmagupta. Thus we have two Vāsiṣṭha Siddhāntas and two Romaka Siddhāntas). My personal view is that Lāṭadeva, Śrīṣeṇa and possibly Viṣṇucandra also, were naturalised Greeks, settled in India and they had adopted themselves to Indian life. They were conversant in Greek and Indian Astronomy both and had contributed substantially to Indian astronomy. Brahmagupta was opposed to any of these foreign influences dominating Indian

—*BrSpSi*. XI. 50

systems, and he very much resented such interferences in pure academic life of this country. He was opposed to Āryabhaṭa for a different reason. Āryabhaṭa was universally regarded as an authority in this country, and the conservatism was so deep that even where it could be shown by direct observation or on valid theoretical grounds, that a particular concept was erroneous or less accurate, people still chose to adhere to it, since they had the backing of Āryabhaṭa's authority. Brahmagupta was against this nonscientific attitude. Needless to say, Brahmagupta was not always fair to Āryabhaṭa in his criticism ; he overdid in enumerating the shortcomings of Āryabhaṭa's system, as if he was personally jealous of his wide popularity.

Brahmagupta's feelings against Lāṭadeva, Śrīṣeṇa, Viṣṇucandra and others would be seen from the following passage in the *Brahmasphuṭasiddhānta* :

From the fact that Śrīṣeṇa, Viṣṇucandra, Pradyumna Āryabhaṭa, Lāṭa, and Simha contradict one another regarding eclipses and similar topics, their ignorance, is proved daily. The criticisms which I have passed on Āryabhaṭa are, with the requisite modifications, to be applied to the doctrines of each of these teachers as well. I will, however, make some further critical remarks on Śrīṣeṇa and others.

Śrīṣeṇa took from Lāṭa the rules concerning the mean motions of the Sun, and the Moon, the Moon's apogee and her node, and the mean motions of Mars, Mercury's Śighra, Jupiter, Venus's Śighra, and Saturn ; he took elapsed years and the revolutions of *yuga* (*yuga-yāta-varṣa-bhagaṇa*) from Vasiṣṭha and the *Padakarana* of Vijayanandi ; further took from Āryabhaṭa the rules concerning the apogee, epicycles and nodes, and those referring to the true motions of the planets and thus the Romaka Siddhānta which was (or is) a heap of jewels (as it were) has, by Śrīṣeṇa, been made into a patched rag (as it were)¹.

1. श्रीदिग्विष्णुचन्द्र प्रद्युम्नार्यभट्टसिद्धान्तम् ।
ग्रहणादिकिंवादात् प्रतिदिक्कं दिगुणमन्त्रत्वम् ॥

Brahmagupta very emphatically says about his system that so long as people would be finding concordance between the observed and theoretical results (*dyggaṇitaikyam*) in respect of solar and lunar eclipses, his Brāhma Siddhānta would be held in esteem¹.

In other systems, whatever concordance appears to be between the observation and calculation, of eclipses etc., it is, Brahmagupta says, merely accidental or by chance, as the maxim of letters bored by an insect in wood or paper².

Brahmagupta and Astronomical Instruments

The Twenty-second Chapter of the *Brāhmasphuṭasiddhānta* is known as the *Yantrādhyāya* or a chapter on instruments. There is a description of seventeen types of time-reckoning instruments (*Kāla-yantra*)¹ :

1. Dhanuryantra—Bow instrument.
2. Turyagolaka yantra—Quadrant (one-fourth sphere)
3. Cakra yantra=wheel or circle.
4. Yaṣṭi yantra—a pole or staff instrument.
5. Śaṅku yantra—Gnomon.
6. Ghaṭikā yantra—a clock or pot instrument.
7. Kapāla yantra—Bowl or potsherd instrument.
8. Karttari yantra—Scissor or knife ; cutter.
9. Piṭha yantra=Pedestal or seat instrument.
10. Salila yantra—Water-leveller.
11. Brahma or Śāṇa yantra—For describing circles.
12. Avalamba Sūtra—Threads with plumbs (Plumb lines).
13. Kārṇa or chāyā-kārṇa—A set of squares for diagonals.
14. Chāyā or śaṅku-chāyā—Sundial.

1. सप्तदश कालयन्त्राण्यतो धनुस्तुर्यगोलकं चक्रम् ।
यष्टिः शङ्कुर्वटिका कपालकं कर्चरी पीठम् ॥
सलिलं भ्रमीऽवलम्बः कर्णशङ्खाया दिनार्धमर्कोऽक्षः ।
नतकालज्ञानार्थं तेषां संसाधनान्यथै ॥

15. Dinārdha yantra—Midday measure instrument.
16. Arka yantra—Sun-instrument.
17. Akṣa or Palāṅśa yantra—Small degree measure arc instrument.

Salila yantra is used for levelling; since a liquid such as water seeks its own level, it can be utilised to know whether a surface has been levelled or not.¹ *Bhrama* or *Śāna* is used for drawing circles. *Avalambaka* or plumbline is used for adjusting vertical line. *Karṇa* is used in connection with angles and diagonals. From *Salila* (no. 10) to the last (no. 17); these eight are used for adjustments and are basically important.

The *dhanuryantra* is used for *nata* and *unnata* *kāla ghaṭikās*.

On the *paridhi* or the circumference of the *cakra-yantra* are indicated the twelve *rāsis*, ending up to Mīna (XXII. 18). Brahmagupta has described the *yaṣṭi yantra* and shown how it could be used to give time at different parts of the day, and from its shadow *dṛggyā* and other characteristics can be calculated. This instrument can also be used for ascertaining the solar-lunar differences, and for fixing up the directions. It can be used for determining various heights and altitudes.

The *karttari yantra* is of the shape of a pair of scissors with two semi-circular blades, fastened to a string at the centre; at the centre is fixed a pin or a pole which casts shadows.

Setting up of the Gnomon

Here it would be interesting to describe the setting of a gnomon, which K.S. Shukla has given in details while commenting on the *Mahābhāskariya* (IV. 1):

After having tested the level of the ground by means of water, draw a neat circle with a pair of compasses (*barkatā*) (At the centre of that circle, set up a vertical gnomon). The gnomon should be large, cylindrical, massive, and tested for its perpendicularity by means of four threads with plumbs (*avalmbaka*) tied to them.

1. सखिलेन समं साध्वं त्रयेण वृत्तमवलम्बकेनोर्ध्वम् ।

तिर्यक् कर्षेनान्यैः कथितैश्च नव प्रवक्ष्यामि ॥

Bhāskara I in his commentary on the *Āryabhaṭīya* tells us that there was a difference of opinion amongst astronomers in his time regarding the shape and size of gnomon (also called style). Some astronomers prescribed a gnomon with its one-third in the bottom of the shape of a prism on a square base (*caturasra*), one-third in the middle of the shape of a cow's tail (*go-pucchākāra*), and one-third at the top of the shape of a spear-head (*Śulākāra*) and some others prescribed a square prismatic (*samacaturasra*), gnomon. The followers of Āryabhaṭa I, he informs us, prescribed the use of a broad (*prthu*), massive (*guru*), and large (*dirgha*) cylindrical gnomon, made of excellent timber and free from any hole, a scar or knot on its body. In the above stanza, Bhāskara I prescribes this last kind of gnomon: the other two kinds he proves in the commentary to be defective and so he rejects them.

For getting the shadow^{end} easily and correctly the cylindrical gnomon was surmounted by a fine cylindrical iron or wooden nail fixed vertically at the centre of the upper end. The nail was taken to be longer than the radius of the gnomon, so that its shadow was always seen on the ground.

Certain writers, Bhāskara I tells us in the commentary, prescribed a gnomon of half a cubit (=12 *āṅgulas*) in length and having twelve divisions. But according to Bhāskara I (although it was the usual custom) there was no such hard and fast rule. The gnomon could be of any length and any number of divisions. The gnomon should, however, be large enough, so that the rings of graduation on the gnomon may be clearly seen on the shadow. A broad and massive gnomon was preferred because it was unaffected by the wind.

Brahmagupta describes gnomon which at the bottom is two *āṅgulas* wide, pointed as a needle, 12 *āṅgulas* in length, and full of holes from the basic circular part to the pointed extremity. (*BrSpSi*. XXII. 39).

As regards testing the level of the ground, Bhāskara I observes :

When there is no wind, place a jar (full) of water upon a tripod on the ground which has been made plane by means of eye or thread, and bore a (fine) hole (at the bottom of the jar) so that the water may

have continuous flow. Where the water falling on the ground spreads in a circle, there the ground is in perfect level ; where the water accumulates after departing from the circle of water, it is low ; and where the water does not reach, there it is high. (Bhāskara's Commentary on the *Āryabhaṭṭya*, II. 13).

After the ground was levelled, a prominently distinct circle was drawn on the ground as stated in the text (*MBh.* III. 1). In the time of Sankaranārāyaṇa (869 A.D.), there it seems that all lines were drawn on the ground with sandal paste (*candanā-kṣodārdra*). The above circle having been thus drawn and coated with sandal paste, another small concentric circle was drawn with the radius of the gnomon. The gnomon was then placed vertically with the periphery of its base in coincidence with that circle. The gnomon was thus set up exactly in the middle of the bigger circle. The verticality of the gnomon was tested by means of four plumb lines hung on the four sides of the gnomon

Gnomon Used for Finding the Directions

The rule in this connection has been described by Brahmagupta in *BrSpŚi.* III. 1. The same rule in other words has been described by Bhāskara I in *MBh.* III. 2. In the *Yāsanā Bhaṣya*, Pīṭhūḍaka Svāmī describes the details of determining the directions. The level of the ground is ascertained by means of water and a gnomon of 12 *āṅgulas* is set up. Find out two points where the shadow of the gnomon enters into and passes out of the circle. Bhāskara prescribes drawing out a fish figure with these points. The thread line which goes through the mouth and tail of the fish figure indicates the north and south directions with respect to the gnomon. Brahmagupta says that if the Sun is on the eastern side, then where the shadow-point enters circle (in the forenoon) that point would be the west, and the point where it emerges out (in the afternoon) is the east.

As the Sun moves along the ecliptic, its declination changes. By the time the shadow moves between the forenoon and afternoon points as given above, the Sun traverses some distance of the ecliptic and, so, theoretically speaking, its

declination gets changed. It follows, therefore, that the East-West line in the above determination is not the true position of the actual East-West line. *Brahmagupta* (628 A. D.) was the first Hindu astronomer who prescribed the determination of the East-West line with proper allowance for the change in the Sun's declination. (Shukla) The details of the method intended by him have been supplied by his commentator *Prthūdaka Svāmī* (860 A. D.).

Bhāskara and Brahmagupta both give another method of determining directions : (*BrSpSi.* III. 2; *MBh.* III. 3) : With the three points (at the ends of the three shadows of the gnomon) corresponding to (any three) different times (in the day), draw two fish-figures (each with two of the three points) in accordance with the usual method. From the point of intersection of the lines passing through the mouth and tail (of the two fish-figures), determine the north and south directions. (*MBh.* III. 3).

Brahmagupta in his rule is more precise :

The point where the lines passing through the two fish-figures, which are drawn by means of three shadow ends (of the gnomon), intersect each other is for places in the northern hemisphere, the south direction, (if the midday shadow falls to the north of the foot of the gnomon). If the midday shadow falls towards the south of the foot of the gnomon, it is the north direction. (*BrSpSi.* III. 2).

This rule is obviously based on the assumption that the locus of the end of the shadow of the gnomon is a circle. In fact the locus for places whose latitude is less than $(90^\circ - \text{the obliquity of the ecliptic})$, this locus is a hyperbola.

Brahmagupta has made numerous uses of gnomon. He and Bhāskara, for example, both give the rules for finding the latitude and colatitude and the zenith distance and altitude of the Sun by finding out the length of the shadow and the length of the gnomon (*BrSpSi.* III. 10; *MBh.* III. 5); also rule for the determination of the latitude with the help of the Sun's meridian zenith distance and declination (*BrSpSi.* III. 13; *MBh.*

III. 17); also rule for finding the Sun's altitude (*BrSpSi*. III. 27; *MBh*. III. 24) (The Sun's altitude for the night has been called by Brahmagupta as *pātala-śanku*, *BrSpSi*. XV. 9).

Golayantra or Armillary Sphere

The first mention of the Golayantra or the armillary sphere is in the *Aryabhaṭīya* (Golapāda. 22)¹ which was a uniformly round circle made of wood or of bamboo and which was of uniform weight or density alround. It was levelled with mercury, oil or water. A śalākā or pin (or rod) was fixed in it in the south-north direction. Its description from the commentary *Bhaṭṭadīpikā* of Paramādiśvara is given here :

A sphere of wood, uniformly round on all sides and with uniform density, and also light is made to revolve round an iron axis fixed north-south without friction (oil may be introduced to avoid friction). To the backside of the sphere, is fixed a *nālaka* full of water which has the length equal to the circumference of the sphere: and which has a hole at the bottom.

Now a thread, connected to the hook of the wooden ball (on the top side) passing over another small ball (in the same axis of the wooden ball) is attached to the mercury lobe by its other end. The mercury lobe is placed on the level of water and water is allowed to flow through the bottom hole and with water mercury lobe also goes down. The time in which the above hook of ball comes to bottom (180°) is noted.

The experiment is repeated with oil. The use of this mechanism is to revolve the ball by water or oil¹

[Cont. on Page 337]

In the Arabic epitome of the Almagest entitled *Tahriru'l mejesti*. the armillary sphere, *Za ul halk*, is thus described :

Two equal circles are placed at right angles, the one representing the ecliptic, the other the solstitial colure. Two pins pass through the poles of the ecliptic and two other pins are placed on the poles of the equator. On the first two pins are suspended a couple of circles moving, the one within, the other without, the first mentioned circles, and representing two secondaries of the ecliptic. On the two other pins a circle is placed, which encompasses the whole instrument, and within which the different circles turn; it represents the meridian. Within the inner secondary of the ecliptic, a circle is fitted to it, in the same plane and turning in it. This is adapted to measure latitudes. To this internal circle, two apertures or sights, opposite to each other, and without its plane are adapted like the sights of an instrument for altitudes. The armillary sphere is complete when consisting of these six circles. The ecliptic and secondaries are to be graduated as minutely as may be practicable. It is best to place both secondaries, as by some directed, within the ecliptic (instead of placing one of them without it), that the complete revolution of the outer secondary may not be obstructed by the pins at the poles of the equator. The meridian likewise should be doubled, or made to consist of two circles; the external one graduated and the internal one moving within it. Thus the pole may be adjusted at its proper elevation above the horizon of any place. The instrument so constructed consists of seven circles.

It is remarked that when the circle representing the meridian, is placed in the plane of the true meridian, so

SaSi. XIII, 16-17

that it cuts the plane of the horizon at right angles, and one of the poles of the equator is elevated above the horizon conformably with the latitude of the place; then the motions of all the circles round the poles represent the motions of the universe.

After rectifying the meridian, if it be wished to observe the Sun and Moon together, the outer secondary of the ecliptic must be made to intersect the ecliptic at the Sun's place for that time: and the solstitial colure must be moved until the place of intersection be opposite to the Sun. Both circles are thus adjusted to their true places; or if any object but the Sun, be observed, the colure is turned until the object be seen in its proper place, on that secondary referred to the ecliptic: the circle representing the ecliptic being at the same time in the plane of the true ecliptic and in its proper situation. Afterwards, the inner secondary is turned towards the Moon (or to any star intended to be observed), and the smaller circle within it, bearing the two sights is turned, until the Moon, (or to any star intended to be observed), and the smaller circle within it, bearing the two sights, is turned, until the Moon be seen in the line of the apertures. The intersection of the secondary circle and ecliptic is the place of the Moon in longitude: and the arc of the secondary, between the aperture and the ecliptic, is the latitude of the Moon on either side (North or South). (From Colebrooke's *Miscellaneous Essays*).

The same instrument, as described by Montucla from the text of Ptolemy (l. 3. c. 2) consists of six circles: first a large circle representing the meridian; next four circles united together, representing the equator, ecliptic and two colures, and turning within the first circle on the poles of the equator, lastly a circle turning on the poles of the ecliptic, furnished with sights and nearly touching, on its concave side, the circumference of the ecliptic.

The armillary sphere described by the Arabian epitomiser, differs, therefore, from Ptolemy's in omitting the equator and

equinoctial colure, and adding an inner secondary of the ecliptic, which as well as the meridian, is doubled.

According to Lalande, the astrolabe of Ptolemy, from which Tycho Brahe derived his equatorial armillary, consisted only of four circles: two placed at right angles to represent the ecliptic and solstitial colure; a third turning on the poles of the ecliptic and serving to mark longitudes; and a fourth, within the other three, furnished with sights to observe celestial objects and measure their latitudes and longitudes.

Whether the ancient Greeks had any more complicated instrument formed on similar principles, and applicable to astronomical observations, is perhaps uncertain. We have no detailed description of the instrument which Archimedes is said to have devised to represent the phenomena and motions of the heavenly bodies; nor any sufficient hint of its construction; nor does Cicero's account of the sphere exhibited by Posidonius suggest a distinct notion of its structure.

Among the Arabs, no addition is at present known to have been made to the armillary sphere; between the period when the *Almagest* was translated and the time of Alhazen, who wrote a treatise of optics, in which a more complicated instrument than that of Ptolemy, is described; Alhazen's armillary sphere is stated to have been the prototype of Tycho Brahe's; but neither the original treatise, nor the Latin translation of it, are procurable and one is therefore unable to ascertain whether the sphere, mentioned by the Arabian author, resembled that described by Indian astronomers. At all events, says Colebrooke, he is more modern than the oldest of the Hindu writers.

Here we give the literal translation of the passage on armillary sphere or *Golayantra* occurring in the *Sūrya-Siddhānta* :

Let the astronomer frame the surprising structure of the terrestial and celestial spheres.

Having caused a wooden globe to be made (of such size) as he pleases; to represent the Earth : with a staff for the axis passing through the centre, and exceeding the globe at both ends; let him place the supporting hooks, as also the equinoctial circle.

Three circles must be prepared, (divided for signs and degrees), the radius of which must agree with the

respective diurnal circles, in proportion to the equinoctial: the three circles should be placed for the Ram (*Meṣa*) and following signs, respectively, at the proper declination in degrees N. or S. ; the same answer contrariwise for the Crab (*Karkatā*) and other signs. In like manner three circles are placed in the southern hemisphere, for the Balance (*Tulā*) and the rest, and contrariwise for Capricorn (*Mr̥ga*) and remaining signs. Circles are similarly placed on both hoops for the asterisms in both hemispheres, as also for *Abhijit* and for the *Seven R̥sis*, *Agastya*, *Brahmah̥daya* and other stars.

In the middle of all these circles is placed the equinoctial. At the intersection of that and supporting hoops, the distant from each other half the signs, the two equinoxes should be determined; and the two solstices, at the degrees of obliquity from the equinoctial; and the the places of the Ram (*Meṣa*) and the rest, in the order of the signs, should be adjusted by the strings of the curve. Another circle thus passing from equinox to equinox, is named the ecliptic; and by this path, the Sun illuminating worlds, for ever travels. The Moon and other planets are seen deviating from their nodes in the ecliptic to the extent of their respective greatest latitudes (within the zodiac).¹

[Cont. on page 341]

The author of the *Sūrya-Siddhānta* then proceeds to notice the relation of the great circles before mentioned to the horizon, and observes that whatever place be assumed for the apex of the sphere, the middle of the heaven for that place is its horizon. He concludes by showing, that the instrument may be made to revolve with regularity, by means of a current of water; and hints, that the appearance of spontaneous motion may be given, by a concealed mechanism, for which quicksilver is to be employed. There is a hint of secrecy also in one of the lines, and it has, therefore, been stated that the construction and the mechanism of working should be learnt under the guidance of a teacher.

How to Observe Places of Stars

Details are not available in this connection. The *Sūrya-Siddhānta* only hints "that the astronomer should frame a sphere and examine the apparent longitude and latitude (*sphuṭavikṣepa* and *sphuṭadhruvaka*)". The commentators, however, describe the manner of making the observation. They direct a spherical instrument (*Golayantra*) to be constructed as described above. This instrument is very much similar to the armillary sphere. An additional circle graduated for degrees and minutes, is directed to be suspended on the pins of the axis as pivots. It is named as *Vedhavalaya* or intersecting circle, and appears to be a circle of declination. After noticing this addition to the instrument, the instructions proceed to the rectifying of the *Golayantra* or armillary sphere which is said to be placed, so that the axis shall point to the pole: and the horizon be true by a water level.

The instrument being thus placed, the observer is instructed to look at the star *Revati* through a sight fitted to an orifice at the centre of the sphere; and having found the star, to adjust by it the end of the sign *Pisces* on the ecliptic. The observer is then to look through the sight, at the *yoga* star of *Āśvinī*, or at

SuSi. XIII. 3-12

some other proposed object; and to bring the moveable circle of declination over it. The distance in degrees, from the intersection of this circle and ecliptic, to the end of *Mina* or Pisces, is its longitude (*dhruvaka*) in degrees; and the number of degrees on the moveable circle of declination, from the same intersection to the place of the star, is its latitude (*vikṣepa*) North or South.

The commentators have rightly remarked that the 'latitude so found is *sphuṭa* or apparent, being the place intercepted between the star and the ecliptic, on a circle passing through the poles; but the true latitude (*asphuṭa*) is found on a circle hung upon the poles of the celestial sphere as directed in another place". (From Colebrooke's Paper on the Indian and Arabian Divisions of the Zodiac. *Miscellaneous Essays*, Vol. II, 324-326).

For the details of the *Golayantra*, readers are requested to refer to the description in the *Siddhānta-Siromaṇi* of Bhāskara II.

for

- (च) इस प्रति में ‘घ’ की भाँति श्लोक में तीन पंक्तियाँ हैं—पहली पंक्ति है :
 —‘नीचोच्चवृत्तमध्यं मध्ये तद्भ्रमति मध्यमः स्वोच्चात्’
 (ङ) (वि०—इस प्रति की पहली पंक्ति ‘नीचोच्चवृत्तमध्यं तद् भ्रमति मध्यमः स्वोच्चात्’ उपर्युक्त प्रतियों में छूट गई। और दो श्लोकों की चार पंक्तियों में से केवल तीन को सम्मिलित करके एक श्लोक माना गया। आगे के श्लोकों में फलतः सर्वत्र इस प्रति की दृष्टि से पूर्व श्लोक का उत्तरार्ध + अग्रिम श्लोक का पूर्वार्ध मिलाकर श्लोकों की व्यवस्था की गई है।

स्पष्टं तन्मध्यांतरमृणं धनं वा तप्तो मध्ये ।
 कोटिफलं व्यासार्द्धात्पदयोराद्यंतयो भवत्युपरि ॥ २६ ॥
 द्वितृतीययोर्यतोऽधस्ताष्टुक्तोनं तरतः कोटिः ।
 कर्णस्तद्भुजफलकृतिसंयोग पदं तदुद्धृता त्रिज्या ॥ २७ ॥
 भुजफल गुणिताप्तधनु गुणिते चैवं फलं शीघ्रे ।
 त्रिज्याभक्तः कर्णः परिधिगुणो बाहुकोटिः गुणाकारः ॥ २८ ॥

२६. (घ) १. अष्टं for (स्पष्टं)

२. ततो (ग) गृहे मध्ये ॥ २६ ॥ for (तप्तो मध्ये)

३. भवत्युपरि (ग) (च) (ङ) for (भवत्युपरि)

(ग) इस श्लोक की पहली पंक्ति २६ वें श्लोक की दूसरी पंक्ति है ।

इस श्लोक की दूसरी पंक्ति २७ वें श्लोक की पहली पंक्ति हैं—

(च) २. ततो for (तप्तो)

(ङ) दे० वि० नोट २५ वें श्लोक के अन्तर्गत टिप्पणी में ।

२. गृहे मध्ये for (तप्तो मध्ये)

२७. (घ) १. तद्युक्तोनं (ङ) for (ताष्टुक्तोनं) २. तरतः (ङ) for (तरतः)

(ग) ३. कोटिः ॥ २७ ॥ (ङ) for (कोटिः)

(वि०—इस श्लोक की दूसरी पंक्ति—२८ वें श्लोक की प्रथम पंक्ति है—

४. फलसंयोगं for (फलकृति संयोग)

(च) १. अधस्ताष्टुक्तोनं for (अधस्ताष्टुक्तोनं)

२८. (घ) १. धनुर्गुणिते for (धनुगुणिते) (ग) गुणितेनैवं फलं शीघ्रे ॥ २८ ॥

२. नैवं for (चैवं)

३. त्रिज्या for (त्रिज्या)

४. गुणो (ग) (ङ) for (गुणो)

५. गुणाकारः (ग) (ङ) for (गुणाकारः)

(ग) इस श्लोक की पहली पंक्ति २८ वें श्लोक की द्वितीय पंक्ति है ।

६. भुजफल for (भुजफल)

७. कोटि (ङ) for (कोटिः)

(च) १. गुणिते for (गुणिते)

४. परिधिगुणो for (परिधिगुणो)

७. कोटि for (कोटिः)

५. गुणाकारः for (गुणाकारः)

(ङ) १. धनुर्गुणिते for (धनुगुणिते)

२. नैवं for (चैवं)

३५. (घ) १. दृश्यंते (ङ) for (दृश्यन्ते)

(यहां ३५ की संख्या अङ्कित है)

२. द्वैसंछन्नः (ग) र्वसंछन्नः (ङ) र्व सञ्छन्नः for (संछन्नः)

(ग) ३. पंच for (पंच)

१. दृश्यंते ॥ ३६ ॥ for (दृश्यंते)

४. रादरणं for (रावरणं)

५. कुठ (ङ) for (कुठ)

वि०—इस श्लोक का उत्तरार्ध ३७ वें श्लोक का पूर्वार्ध है)

(च) ६. विक्षेपो for (विक्षेपो)

३. पंचदृश्यंते ३५ for (पंचदृश्यंते)

७. महदिदो (ङ) for (महदिदो)

२. यतोर्द्ध for (यतो)

८. (वि०—यहां कोई क्रमसंख्या अंकित नहीं है)

(ङ) ४. रावरणं for (रावरणं)

३६. (घ) १. स्तीक्ष्ण (ग) (ङ) for (स्तिक्ष्ण)

२. ततोऽस्याल्पम् (च) (ङ) for (ततोऽस्याल्पे)

(वि०—यहां क्रमसंख्या ३६ दी है)

३. प्राग्भागादिदु (ग) प्राग्भादिदु for (प्राग्भादिदु)

(ग) २. ततोऽस्याल्पी ॥ ३७ ॥ for (ततोऽस्याल्पे)

(वि०—इस श्लोक का उत्तरार्ध ३८ वें श्लोक का पूर्वार्ध है)

(च) १. स्तीक्ष्ण for (स्तिक्ष्ण)

४. (वि०—यहां कोई क्रमसंख्या नहीं दी, क्योंकि इस प्रति के अनुसार यहां का उत्तरार्ध ३७ वें श्लोक का पूर्वार्ध है ।

(ङ) ५. अर्धच्छन्तो for (अर्द्धच्छिन्नो)

२. प्राग्भागादिदु for (प्राग्भादिदु)

३७. (घ) १. स्थित्यद्धं for (स्थित्यद्धं)

२. सूर्यः स्य (यहां क्रमसंख्या ३७ दी है) (ग) सूर्यस्य ॥ ३८ ॥ for (सूर्यस्य)

३. विषयं (ग) विषयं for (विषयं)

(ग) (वि०—इस श्लोक का उत्तरार्ध ३९ वें श्लोक का पूर्वार्ध है ।

४. सूर्यो for (सूर्यो)

(च) ५. यथा (ङ) for (यथा)

२. (वि०—यहां क्रमसंख्या ३७ अंकित है)

६. वि०—यहां कोई क्रमसंख्या नहीं दी है, क्यों कि इस श्लोक का उत्तरार्ध, ३९ वें श्लोक का पूर्वार्ध है । (ङ) १. स्थित्यद्धं for (स्थित्यद्धं)

३८. (घ) १. कृतं (ग) (च) (ङ) for (कृतं)

२. मर्कटोः (ग) मर्कटोः ॥ ३९ ॥ for (मर्कटो) (यहां ३८ संख्या दी है)

(ग) ३. श्रीषेणार्यभट for (श्रीषेणार्य)

इस श्लोक का उत्तरार्ध, ४० वें श्लोक का पूर्वार्ध है ।

(च) २. मर्कटोः for (मर्कटोः) (वि०—यहां श्लोक संख्या ३८ अंकित है)

४. यहां क्रमसंख्या लुप्त है, क्योंकि यह ३९ वें श्लोक का पूर्वार्ध है ।

(ङ) २. मर्कटोः for (मर्कटोः)

३९. (घ) १. स्मृत्युवि for (स्मृति) (यहां संख्या ३९ है)

२. संहितासु (ग) (ङ) for (संहितासु)

३. यदि बिहितम् (ग) for (दयभिहितम्)

(ग) ४. संहिताबाह्यम् ॥ ४० ॥ for (संहिताबाह्यम्)

५. यद्येवं ग्रहफलं for (यद्येवं ग्रहणफलं)

(वि०—इस श्लोक का उत्तरार्ध ४१ वें श्लोक का पूर्वार्ध है ।

(च) ४. यहां '३९' की क्रमसंख्या अंकित है । परन्तु उत्तरार्ध के अन्त में कोई क्रमसंख्या अंकित नहीं, क्योंकि उत्तरार्ध, ४० वें श्लोक का पूर्वार्ध माना जाता है ।

(ङ) ३. यदभिहितम् for (दयभिहितम्)

तदभावे^१ होमजपः^२ स्नानादि^३ फलस्य^४ चाभावः^५ ।

राहुकृतं^१ ग्रहरणद्वयं^२ मागोपालांगनादि^३ सिद्धमिदम्^४ ॥ ४० ॥

स्वर्भानुरास्तुरिरिन्^१ तमसा^२ वित्याधवेदवाक्यमिदम्^३ ॥ ४२ ॥

४०. (घ) (वि०—यहाँ प्रथम पंक्ति के अन्त में ४० संख्या दी है)

१. कृतं (ग) for (कृतं)

(ग) २. तदभावो for (तदभावे) ३. लुप्त पद है । ४. लुप्त पद है ।

५. फलस्याभावः ॥ ४१ ॥ for (फलस्य चाभावः)

(वि०—इस श्लोक का उत्तरार्ध, अगले श्लोक का पूर्वार्ध है)

६. मागो पालाङ्गना for (मागो पालाङ्गनादि)

(च) ७. यहाँ '४०' क्रमसंख्या अंकित है । ८. यहाँ कोई संख्या अंकित नहीं, क्योंकि यह उत्तरार्ध भाग ४१ वें श्लोक का पूर्वार्ध माना जाता है ।

(ङ) ४. जप for (जपः) ५. स्नानादीनां फलाभावः for (स्नानादि फलस्य चाभावः)

४१. (घ) १. बाहु for (बहु)

२. मंत्र (यहाँ क्रमसंख्या ४१ दी है) (ग) मन्त्र ॥ ४२ ॥ for (मन्त्र ॥ ४१ ॥)

३. स्मृतिषुक्तं (ग) (ङ) for (स्मृतीषुक्तं)

(ग) इस श्लोक का उत्तरार्ध ३३ श्लोक का पूर्वार्ध है

(च) २. यहाँ '४१' क्रमसंख्या दी गई है । ३. स्मृतीषुक्तं for (स्मृतीषुक्तं)

(वि०—इस प्रति के अनुसार इस श्लोक का उत्तरार्ध ४२ वें श्लोक का पूर्वार्ध है अतः यहाँ अन्त में क्रमसंख्या अंकित नहीं है)

४२. (घ) १. सूर्ये (ग) (च) (ङ) for (सूर्ये)

२. (वि०—यहाँ क्रमसंख्या ४२ (ग) ४३ दी है)

३. रासुरि (ग) रासुरि न तमसा for (रास्तु)

४. विव्याध (ग) विव्याध (ङ) for (वित्याध)

(ग) इस श्लोक का उत्तरार्ध अगले श्लोक का पूर्वार्ध है ।

(च) २. (वि०—यहाँ क्रमसंख्या ४२ अंकित है) ३. रासुरिरिन् for (रास्तुरिरिन्)

४. विव्याध for (वित्याध)

यहाँ श्लोक के अन्त में कोई क्रमसंख्या अंकित नहीं क्योंकि यह उत्तरार्ध माना जाता है ।

(ङ) ३. रासु for (रास्तु)

वि. भा. — महादेवः (शङ्करः) जयति (सर्वोत्कर्षेण वर्त्तते), कीदृशः प्रणत-
सुरासुरमौलिगरत्नप्रभाच्छुरितपादः (प्रणता नतमस्तका ये सुरासुरा देवराक्षसा-
श्च मौलिकानि शिरोगतानि यानि रत्नानि हीरकादीनि तेषां प्रभाभिर्ज्यो-
तिभिः, छुरितौ संमिश्रितौ पादौ चरणौ यस्य सः) पुनः कीदृशः जगदुत्पत्तिस्थिति-
विलयानां (जगतः संसारस्योत्पत्तिः प्रादुर्भावः स्थितिः संरक्षणमवस्थानं वा
विलयो नाशस्तेषां कर्त्ता कारकोऽर्थात्संसारोत्पत्तिस्थितिविनाशानां कारणभूत
इत्येतावता ब्रह्मगुप्तो महादेवमीश्वरं स्वीकरोतीति सिद्धयति, ईश्वरमन्तराऽन्येषां
जगदुत्पत्तिस्थितिविनाशकरणसामर्थ्याभावात् । विषयस्यास्य दर्शनशास्त्रेण सम्ब-
न्धोऽस्त्यतोऽत्र विशिष्य तद्विचारस्याऽवश्यकता नास्ति ॥ १ ॥

हि. भा. — प्रणाम करते हुए देवों और राक्षसों के मस्तक (शिर) पर स्थित रत्नों (हीरा
आदि) की ज्योति से मिश्रित (मिले हुए) हैं दोनों चरण (पाँव) जिनके ऐसे महादेवजी सब
तरह के उत्कर्ष से विद्यमान हैं. पुनः संसार की उत्पत्ति, स्थिति (अवस्थान) और विलय (नाश)
के करने वाले हैं । ब्रह्मगुप्ताचार्य की इस उक्ति से महादेव में ईश्वरत्व सिद्ध होता है, क्योंकि
जगत् की उत्पत्ति, स्थिति और विनाश करने की शक्ति ईश्वर से भिन्न किसी में नहीं हो
सकती । इस विषय का दर्शन शास्त्रों से सम्बन्ध है इसलिए यहाँ उस पर विशेष विचार करने
की आवश्यकता नहीं है ॥ १ ॥

इदानीं ग्रन्थारम्भप्रयोजनमाह ।

ब्रह्मोक्तं ग्रहगणितं महता कालेन यत् श्लथीभूतम् ।
अभिधीयते स्फुटं तज्जिष्णुसुतब्रह्मगुप्तेन ॥ २ ॥

वि. भा. — ब्रह्मोक्तं (ब्रह्मणा कथितं) ग्रहगणितं (ब्रह्मसिद्धान्तः)
यदस्ति महता कालेन श्लथीभूतं जातमर्थाद्विहृषु समयेषु व्यतीतेषु तत्र खिलीभूतत्वं
समागतम् । तत् (तस्मात्कारणात्) जिष्णुसुतब्रह्मगुप्तेन (जिष्णुपुत्रब्रह्मगुप्त
नामकेन मया) स्फुटं (स्पष्टं श्लथीभूतत्वरहितं वा) अभिधीयते ।
अधुनोपलब्धेषु ब्रह्मसिद्धान्तेषु शाकल्यसंहितान्तर्गत एकः, विष्णुधर्मोत्तर-
पुराणान्तर्गतो गद्यमयो द्वितीयः, पञ्चवर्षमययुगवर्णनप्रत्मको वराहमिहिर-
रचितपञ्चसिद्धान्तिकान्तर्गतस्तृतीयः । एतेषां मध्ये ब्रह्मगुप्तेन कृतमः

स्फुटोऽभिधीयते इति स्पष्टं न कथ्यते, तथापि ग्रहभगणादिगठितमानानां समत्वादिषण्णुधर्मोत्तरपुराणान्तर्गत एव ब्रह्मसिद्धान्तः प्रमाणीभूतत्वेन (आगमत्वेन) स्वीकृतो ब्रह्मगुप्तेन, 'युगमाहुः पञ्चाब्द' मित्यादिना पञ्चवर्षमययुगस्य तन्त्रपरीक्षाध्याये संहिताकारमतं वर्णयितुं ब्रह्मगुप्तस्य मते ज्योतिषवेदाङ्गं ब्रह्ममतं नास्तीति स्पष्टम् । इदं वराहमिहिरमताङ्गत्वं सुगणकैर्बोध्यम् । सिद्धान्ततत्त्वविवेके 'अहो विष्णुधर्मोत्तरं चापि सम्यङ् न बुद्धमिति' कमलाकरोक्तादपि तदेव सिद्धयति । बहुषु समयेषु व्यतीतेषु तत्र ब्रह्मसिद्धान्ते कीदृशी श्रुतीभूतता समागता तन्निराकृति-ब्रह्मगुप्तेन कीदृशी कृतेति ब्राह्मस्फुटसिद्धान्ते कुत्रापि नोपलभ्यते । तत्कथनं तथ्यमतथ्यं वेति विवेचका गणितिका विवेचयन्तिवति ॥ २ ॥

अब ग्रन्थारम्भ करने के कारण को कहते हैं ।

हि. भा.—ब्रह्मा से कथित ग्रहगणित (ब्रह्मसिद्धान्त) जो है, बहुत समय में (कालान्तर में) उसमें खिलत्व आ गया है इसलिए मैं जिष्णुपुत्र ब्रह्मगुप्त उसको स्पष्ट कहता हूँ । इस समय ब्रह्मसिद्धान्त तीन प्रकार के उपलब्ध होते हैं । एक शाक्यसंहितान्तर्गत, द्वितीय विष्णुधर्मोत्तरपुराणान्तर्गत गद्यमय और तृतीय पञ्चवर्षमययुगवर्णनात्मक वराहमिहिरकृत पञ्चसिद्धान्तिकान्तर्गत, इन तीनों में ब्रह्मगुप्ताचार्य किसको स्फुट करते हैं इस बात को स्पष्टरूप से नहीं कहते हैं तथापि पठित ग्रहभगणादिमानों के समत्व के कारण विष्णुधर्मोत्तरपुराणान्तर्गत ही ब्रह्मसिद्धान्त को ब्रह्मगुप्त आगमत्व करके स्वीकार करते हैं, पञ्चवर्षमय युग के तन्त्रपरीक्षाध्याय में 'युगमाहुः पञ्चाब्द' इत्यादि से संहिताकार के मत को वर्णन करते हुए ब्रह्मगुप्त के मत में ज्योतिष वेदाङ्ग ब्रह्ममत नहीं है, यह स्पष्ट है । वराहमिहिराचार्य के मत से यह विरुद्ध है इसका गणक लोग विचार करें । सिद्धान्ततत्त्वविवेक में 'अहो विष्णुधर्मोत्तरं चापि सम्यङ् न बुद्धम्' इत्यादि कमलाकरोक्ति से भी स्पष्ट है । बहुत समय में (कालान्तर में) उस ब्रह्मसिद्धान्त में कौंसी श्रुतीभूतता आ गई और ब्रह्मगुप्त ने उनके निराकरण किस तरह किये, ये बातें ब्राह्मस्फुटसिद्धान्त में कहीं भी नहीं पाई जाती हैं, उनके कथन ठीक हैं या नहीं, विवेचक ज्योतिषी लोग विचार करें ॥ २ ॥

इदानीं ज्योतिःशास्त्रमूलभूतस्य सग्रहस्य भचक्रस्य चलनमाह ।

ध्रुवताराप्रतिबद्धज्योतिश्चक्रं प्रदक्षिणगमादौ ।

पौष्णान्ध्रिन्वन्तस्थैः सह ग्रहैर्ब्रह्मणा सृष्टम् ॥३॥

वि. भा.—पौष्णान्ध्रिन्वन्तस्थैः (पौष्णं रेवती, अश्विनी, तयोर्मध्य - (सन्धि-) स्थितैः) ग्रहैः (सूर्यादिभिः) सह (साकं) ध्रुवताराप्रतिबद्धज्योतिश्चक्रं (ध्रुवद्वयगतरेखा ध्रुवयष्टी ध्रुवाक्षो वा तन्निबद्धं ज्योतिश्चक्रं ज्योतीषि क्षेत्रमयानि नक्षत्राण्यन्यानि विशिष्टानि च तेषां चक्रं समूहं) (भचक्रमित्यर्थः)

प्रदक्षिणगम् (दक्षिणावर्तक्रमेण चलायमानम्) आदौ (सर्वप्रथमं) ब्रह्मणा (जगदुद्वादकेन) सृष्टम् (रचितम्) अर्थादश्विन्यादौ स्थितेश्चन्द्रादिभिस्तदुच्चतादिभिश्च साकं ध्रुवयष्टिआधारेण भ्रमणशीलं ज्योतिर्मयपदार्थानां नक्षत्रादीनां चक्रं (गोलं) ब्रह्मणा रचितं यद्यप्यत्राचार्येणोच्चादीनां चर्चा न क्रियते तेषां स्वरूपाभावात् किन्तु सृष्ट्यादिकाले तेषामपि स्थानाङ्कनरूपसर्जनं कृतमिति ॥३॥

अत्र ज्योतिश्चक्रशब्देन भचक्रम् । भानां चक्रं भचक्रमेतावता यत्र भानि सन्ति स च गोलाकारः पदार्थः तदेव भचक्रशब्देन व्यवह्रियते, भचक्रे कथं गोलत्वं, भचक्रचलनज्ञानं, ग्रहाणां कथं पूर्वाभिमुखी गतिः चन्द्रादिग्रहाणां (चन्द्रबुधशुक्ररविकुजगुरुशनीनां) कथमेवमूर्ध्वाधः क्रमेण स्थितिरित्यादि-विविधविषयाणां विचारार्थं वटेश्वरसिद्धान्तोऽप्यवलोकनीयः भास्कराचार्येणापि 'सृष्ट्वा भचक्रं कमलोद्भवेन ग्रहैः सहैतद्भ्रमणादिसंस्थै' रित्यादिना ब्रह्मगुप्तोक्तानुरूपमेव सर्वं कथितमिति ॥ ३ ॥

अब ज्योतिःशास्त्र के मूलभूत ग्रहसहित भचक्रचलन को कहते हैं ।

हि. भा.—रेवती नक्षत्र और अश्विनी के मध्य में (सन्धि में) ग्रहों के साथ ध्रुवाक्ष (दोनों ध्रुवों में गई हुई रेखा) में बंधे हुए दक्षिणावर्त क्रम से भ्रमणशील ज्योतिश्चक्र (भचक्र) को सब से पहले ब्रह्मा ने बनाया अर्थात् अश्विन्यादि में स्थित चन्द्रादिग्रह और उनके उच्चदियों के साथ ध्रुवयष्टि के आधार पर भ्रमणशील नक्षत्र आदि ज्योतिर्मय पिण्डों के चक्र (गोल) को ब्रह्मा ने बनाया । यद्यपि यहां आचार्य उच्च आदि की चर्चा नहीं करते हैं क्योंकि उनके स्वरूप ग्रहों की तरह नहीं हैं किन्तु सृष्टि के आदिकाल में उनका भी स्थानाङ्कन किया ॥ ३ ॥

यहां ज्योतिश्चक्र शब्द से भचक्र समझना चाहिए । भचक्र (नक्षत्रों के गोल) शब्द से ज्ञात होता है कि नक्षत्र और ग्रह, सब जहां देखा जाता है गोलाकार पदार्थ हैं, उसी को भचक्र कहा गया है । भचक्र में गोलत्व क्यों है, भचक्रचलन क्या है और उसका ज्ञान कैसे होता है, ग्रहों की पूर्वाभिमुख गति क्यों है, ग्रहों (चन्द्र, बुध, शुक्र, रवि, भीम, गुरु, शनि) की इस तरह ऊर्ध्वाधः क्रम से स्थिति क्यों है, इत्यादि अनेक विषयों के विचार के लिए वटेश्वर सिद्धान्त का मध्यमाधिकार देखना चाहिए । भास्कराचार्य भी 'सृष्ट्वा भचक्रं कमलोद्भवेन ग्रहैः सहैतद्भ्रमणादिसंस्थै' इत्यादि से ब्रह्मगुप्त के अनुरूप ही कहते हैं ॥३॥

इदानीमनाद्यनन्तस्य कालस्य प्रवृत्तिमाह ।

वि. मा.—सृष्ट्यादौ (सृष्ट्यादिकाले) चैत्रसितादेः (चैत्रशुक्लप्रति-
पदादितः) लङ्कायां भानोरुदयात् (लङ्कासूर्योदयकालात्) अर्कस्य दिने (रविवारे)
दिनमासवर्षयुगकल्पाः समं (एककालावच्छेदेन) प्रवृत्ता बभूवुरिति शेषः ।
व्यापकस्यानाद्यनन्तस्य कालस्य विभागो दिनमासवर्षयुगकल्पद्वारा लोक-
व्यवहारार्थं कृतोऽस्ति, एतेषामेव विभक्तकालावयवानां (दिनमासवर्षादीनां)
सृष्ट्यादिकाले एककालावच्छेदेन प्रवृत्तिर्नामादिर्भवति, तथा च सृष्ट्यन्ते (प्रलयकाले)
तेषामेव विभक्तकालावयवान्नामतो भवतीत्येतदनुसारेणैवावतरणे ‘अनाद्यनन्तस्य
कालस्य’ इत्यादिलेखनं युक्तियुक्तं भवितुमर्हति, कथमन्यथा व्यापककालस्य
प्रवृत्तिकथनं युक्तियुक्तं सङ्गच्छते । भास्कराचार्येणापि सिद्धान्तशिरोमणी
‘लङ्कानगर्यामुदयाच्च भानोस्तस्यैव वारे प्रथमं बभूव’ इत्यादिना ब्रह्मगुप्तेक्तानु-
रूपमेव कथ्यत इति ॥ ४ ॥

अब अनादि (जिसका आदि नहीं) और अनन्त (जिसका अन्त नहीं है) इस काल
की प्रवृत्ति कहते हैं ।

हि. मा.—चैत्र शुक्ल प्रतिपदादि से लङ्का में सूर्योदयकाल से रवि के दिन में
सृष्ट्यादि (चैत्रशुक्ल प्रतिपदा रविवार लङ्कासूर्योदयकाल) में दिन मास वर्ष युग और
कल्प इन सब की प्रवृत्ति एक ही समय में हुई । यहाँ व्यापक काल (जिसका आदि नहीं है
और अन्त नहीं है) का विभाग दिन, मास, वर्ष, युग, कल्प के द्वारा लोकव्यव-
हार के लिए किया गया है । इन्हीं विभक्त कालावयवों (दिनमास-वर्ष आदि) की
प्रवृत्ति सृष्ट्यादि काल में एक कालावच्छेदेन होती है और सृष्टि के अन्त (प्रलयकाल) में
उन्हीं कालों का अन्त इसी के अनुसार अवतरण में, ‘अनाद्यनन्तस्य कालस्येत्यादि’
लिखना युक्तिसङ्गत होता है । ऐसा यदि नहीं होगा तो फिर व्यापक काल की

प्रवृत्ति कैसे युक्तियुक्त हो सकेगी । भास्कराचार्य भी सिद्धान्तशिरोमणि में 'लङ्का-नगर्यामुदयाच्च भानोस्तस्यैव वारे प्रथमं बभूव' इत्यादि से ब्रह्मगुप्तोक्तानुरूप ही कहते हैं इति ॥ ४ ॥

वि. भा.—अथाऽत्र शास्त्रे पृथिव्याः सम्बन्धेनैव ग्रहादिकक्षादीनां सर्वोपयोगि-विषयाणां ज्ञानं भवत्यत एतस्या आकृतिः कीदृशी तत्परिमाणं च कियदिति निर्णयार्थं विचारः । कुत्रचिद् वृक्षादिविरहितसमभुवि कियद्दूरस्थेष्टिकास्तम्भाग्रस्योद्दीपितशीशकषट्प्रदीपं निशायां दृष्ट्वा किमिदमिति साशङ्को गतस्तत्संमुखम् । गत्वा चाऽसन्नं स्तम्भमूलेऽप्येकमन्यदीपमवलोक्य दृष्ट्यवरोधकाभावेऽपि कथं न दृष्टमिति विस्मितेन दृष्ट्यवरोधिका भूरेवेत्यनुमितमतो भूपृष्ठे वक्रत्वमस्तीति सिद्धम् ।

हि. भा.—इस ज्योतिष सिद्धान्त में पृथिवी के सम्बन्ध ही से सर्वोद्योगी ग्रहादि कक्षा
ग्रादि का ज्ञान होता है, इसलिए इसकी आकृति कैसी है, उसका परिमाण कितना है, इन सब
के निर्णय के लिए विचार करते हैं। किसी वृक्ष ग्रादि से रहित समान पृथिवी में दूर में इंटों के
बने हुए खम्भ के अग्र में जलते हुए लालटेन को रात में देखकर 'क्या बात है' इस आशङ्का से
उसकी तरफ चले, उसके समीप जाकर खम्भा के जड़ में भी जलती हुई एक लालटेन को देख-
कर दृष्टि के रोकने वाली चीजों के नहीं रहने पर भी क्यों देखने में नहीं आया यह शंका
हुई और विचार करने पर मालूम हुआ कि दृष्टि को रोकने वाली पृथिवी ही है इसलिए पृथिवी
के पृष्ठ में वक्रत्व है। यह सिद्ध हुआ।

चारों तरफ आकाश के बराबर रहने पर पृथिवी ही के ऊपर बहुत जगह पके हुए फल
को गिरता हुआ देखकर भूपृष्ठ-स्थित प्रत्येक बिन्दु में आकर्षण शक्ति है यह अनुमान किया गया।
और मापन करने से वृक्ष के अग्र से गिरे हुए बिन्दु तक बद्धसूत्र < फलों के गिरने के स्थानों से
भिन्न बिन्दुओं से वृक्षाग्र तक सूत्र, इस निर्णय से पृथिवी में बहिःस्थित बिन्दु से पृष्ठस्थ बिन्दु-
गत रेखाओं के बहिःखण्डों से केन्द्रगत रेखा बहिःखण्ड अल्प होता है यह गोलसम्बन्धी स्वाभा-
विक धर्म देखने से इसमें किसी तरह का गोलत्व है यह मन में आया। इसलिए पहले इसमें
गोलत्व कल्पना कर के देखना चाहिए कि इसमें गोलीय धर्म है या नहीं। पृथिवी के ऊपर
दो स्थानों में समान दो खम्भों को गाड़कर एक खम्भा के शीर्ष स्थान से और शीर्ष स्थान से
कुछ हट कर उसी खम्भा में दृष्टि स्थान रखकर दूसरे खम्भा के अग्र को देख किए, दोनों खम्भा
के अग्र में सूत्र बांध दिये तब जो एक त्रिभुज बनता है उसमें स्तम्भाग्र प्रथम दृष्टिस्थान और
उस से भिन्न स्थल में जो दृष्टि स्थान रखे हैं इन दोनों दृष्टिस्थान लगन कोणों को मापन द्वारा
जानकर तथा दृष्टिस्थान द्वयान्तर्गत रेखा को भी मापन से जानकर कोणानुपात से खम्भों
के अग्रान्तर समझकर १८०—२× एक स्तम्भाग्रलगनकोण = वर्धितस्तम्भद्वयोत्पन्नभूकेन्द्र-
लगनकोण क्योंकि दोनों खम्भों से और खम्भों के अग्रान्तर से जो त्रिभुज बनता है वह सम-
द्विबाहुक है। तब कोणानुपात करते हैं—

खम्भों के अग्रगत रेखा × खम्भा के, अग्रगण्य कोणज्या = भूव्यासार्ध + खम्भा = ज्ञातबाहु.
भूकेन्द्रलग्न कोणज्या

इसी तरह दूसरे स्तम्भ प्रमाण के लिए भी करना, उसका प्रमाण भी इतना ही आता है अतः दोनों ज्ञातबाहु—दोनों खम्भा = भूव्यासार्ध, इस तरह प्रत्येक जगह में फल (भूव्यासार्ध) बराबर आता है इसलिए पृथिवी गोलाकार है यह सिद्ध है। अर्थात् भूव्यासार्ध को दूना कर देने से भूव्यास होता है तब 'व्यासे भनन्दाग्निहते विभक्ते खवाणमूर्यः' इससे भूपरिधि का ज्ञान होगा। वस्तुतः पृथिवी का पिण्ड दीर्घपिण्ड के आकार का है लेकिन इसके लघु व्यास, और बृहद्व्यास में बहुत ही कम अन्तर होने के कारण दोनों व्यासों को आचार्य ने बराबर मान लिया।

नाड़ीवृत्त कालवृत्त क्यों है यह कहते हैं।

प्रवह वायुद्वारा भगोल को घुमाने पर भी बहुत वर्षों में भी स्थिरता से प्राप्त ध्रुवतारा से चिह्नित ध्रुवस्थान से किसी तारा के अन्तर दृज्याचाप उपलब्ध नहीं होता है, इसी से समझा गया कि वास्तव भगोल पृष्ठनिष्ठ स्थिर केन्द्र से उत्पन्न नाड़ीवृत्त और ग्रहोरात्र वृत्त के घरातल में स्थिरता है वहाँ एक रूप से प्राप्त प्रवह वायुद्वारा घुमाये हुए लम्हीं दोनों वृत्तों की सहायता से कालगणना उचित है, क्योंकि जिस काल का न आदि है न अन्त है ऐसे काल का रूप आगम प्रमाण से सदा एक रूप है। यही युक्ति प्राचीन और नवीन घटीयन्त्रादि के द्वारा कालज्ञान के लिए है।

व दम्ब तारा का दृज्या चाप स्थिर है और कदम्बस्थान में ताराओं को चल देखते हैं इससे सिद्ध होता है कि प्रवहगति के अलावा भी भ्रमकी कोई गति है वह कदम्बोत्पन्न महद्वृत्त रूप मार्ग में होता है। इस आन्दोलिकाकार गति के कारण प्रवहाधार भ्रमकृत्यागकालिक ब्रह्मा के हाथ का आघात ही हो सकता है। उस महद्वृत्त में प्रवह के नाड़ीवृत्तरूप प्रधान मार्ग से प्रस्तुत गति के कारणभूत भ्रमकचलन का सङ्कलन जितना होता है उतना ही आचार्य पूर्वयानांश और पश्चिमयानांश कहते हैं। उसके साधन पूर्वकथित महद्वृत्त के आधार पर बराबर रहने वाले अतिप्रकाशमान नक्षत्रबिम्ब के या ग्रहबिम्ब के अवलम्बन [आधार] से कर सकते हैं। अतः वेध से भ्रमकचलन ज्ञान करते हैं। पूर्व-कथित महद्वृत्त मार्गनिर्याण के लिए वेधगोलीय और स्थिरगोलीय (भगोलीय) नाड़ीवृत्तघरातलान्तर ज्ञान से तथा वेधगोलीय क्रान्तिज्ञान से भगोलीय क्रान्तिज्ञानप्रकार इसी ग्रन्थ में चन्द्र भ्रमण की उपपत्ति में देखना चाहिए।

द्वितीय दिन में षष्टि ६० दण्डात्मक काल में रवि जिस बिन्दु में प्रथम दिन में के वह बिन्दु याम्योत्तरवृत्त (ध्रुवप्रोतवृत्त) में वहीं पर आया। उसके बाद जितने काल में रवि याम्योत्तरवृत्त में आये उस कालमान को छह से गुणने से रवि के निरक्षदेशीय उदयमानद्वय (विषुवांशद्वय) का अन्तर होता है, क्योंकि याम्योत्तरवृत्त निरक्षदेशीय क्षितिज वृत्त है। पूर्व युक्ति से क्रान्तिज्ञान भी कर लिया; इस तरह अनेक दिनों में करके अपने आगे

एक गोल को रखकर उसमें नाड़ीवृत्त संज्ञक महद्वृत्त की रचना कर उसके किसी इष्ट-बिन्दु से पूर्व पूर्वदिशाक्रम से विषुवांशान्तर दान देकर इष्टबिन्दु और प्रत्येक दानाग्र बिन्दुगत ध्रुवप्रोत वृत्तों में प्रत्येक दिन की क्रान्ति दान देकर दो क्रान्तियों के अग्रगत जो महद्वृत्त किया जायगा वह प्रत्येक क्रान्ति के अग्रगत होता है ऐसा उपलब्ध होता है इसलिए रवि का भ्रमण-मार्ग महद्वृत्त सिद्ध हुआ और वह वृत्त प्रत्येक क्रान्ति के अग्र में गया हुआ है, इस लिए उसका नाम क्रान्तिवृत्त है । इति ।

अब विषुवांशद्वय के अन्तर और क्रान्तिद्वय जानकर इष्टक्रान्तिज्ञान के लिए परम क्रान्ति का आनयन करते हैं ।

यहां संस्कृत में इसी की उपपत्ति में (१) क्षेत्र को देखिये । नाड़ीवृत्त और क्रान्तिवृत्त से उत्पन्न कोण = परमक्रान्ति = य विषुवांशान्तर = वि, मध्याह्नय = र, तब 'मध्यत्रिज्या गुणा प्रान्त्यस्पर्शहतिर्भवेत्' इससे ज्यार × त्रि = कोस्पय × स्पक्रां, तथा त्रि × ज्या (र + वि) = कोस्पय × स्पक्रां, । यहां प्रथम क्रान्ति = क्रां । द्वितीय-क्रान्ति = क्रां,

$$\therefore \frac{\text{ज्यार} \times \text{त्रि}}{\text{स्पक्रां}} = \text{कोस्पय} = \frac{\text{त्रि} \times \text{ज्या (र + वि)}}{\text{स्पक्रां}}, \text{ तब } \frac{\text{ज्यार} \times \text{स्पक्रां}}{\text{स्पक्रां}} = \text{ज्या (र + वि)},$$

चापयोरिष्टयोदोर्ज्यं मिथः कोटिज्यकाहते इत्यादि से ज्या (र + वि) =

$$\frac{\text{ज्यार} \times \text{कोज्यावि} + \text{कोज्यार} \times \text{ज्यावि}}{\text{त्रि}} = \frac{\text{ज्यार} \times \text{स्पक्रां}}{\text{स्पक्रां}} = \text{ज्यार} \times \text{गु} \quad \left| \text{यहां } \frac{\text{स्पक्रां}}{\text{स्पक्रां}} = \text{गु} \right.$$

दोनों पक्षों को त्रि से गुणने से

$$\text{ज्यार} \times \text{कोज्यावि} + \text{कोज्यार} \times \text{ज्यावि} = \text{ज्यार} \times \text{गु} \times \text{त्रि, समशोधन करने से}$$

$$\text{ज्यार} \times \text{गु} \times \text{त्रि} - \text{ज्यार} \times \text{कोज्यावि} = \text{ज्यार} (\text{गु} \times \text{त्रि} - \text{कोज्यावि}) = \text{कोज्यार} \times \text{ज्यावि, परस्पर गुणकाङ्क से भाग देने से—}$$

$$\frac{\text{ज्यार}}{\text{कोज्यार}} = \frac{\text{ज्यावि}}{\text{गु} \times \text{त्रि} - \text{कोज्यावि}} = \text{व्यक्त, दोनों पक्षों को बारह से गुणने से } \frac{\text{ज्यार} \times १२}{\text{कोज्यार}}$$

$$= १२ \times \text{व्यक्त} = \text{रतुल्याक्ष देशीय पलभा इससे जो अक्षांश होगा वही 'र' का मान होगा ।}$$

अथवा उन्हीं दिनों पक्षों को यदि त्रि से गुण देते हैं तो $\frac{\text{ज्यार} \times \text{त्रि}}{\text{कोज्यार}} = \text{त्रि} \times \text{व्य} =$
स्पर = रतुल्याक्षांशस्पर्शरेखा, स्पर्शरेखाक्षण्ड से चाप करने से 'र' का मान ही उस देश का अक्षांशमान होता है, इस पर से 'य' का मानज्ञान सुलभ ही है ।।

अब जिस क्रान्तिवृत्त के आधार पर भवक्र का चलन होता है, वही पूर्वकथित रविभ्रमण मार्ग रूप क्रान्तिवृत्त है इसका निर्णय किया जाता है—ध्रुव के स्थान में कदम्ब, याम्योत्तर वृत्त के स्थान में कदम्बप्रोतवृत्त, नाड़ीवृत्त के स्थान में क्रान्तिवृत्त और अक्षज्या के

स्थान में हृक्षेप लेकर आने चन्द्रभरण की उपपत्ति में प्रदर्शित नाड़ीवृत्ताधरातलान्तर ज्ञान उससे ग्रहगोलीय क्रान्ति के आनयन के लिए जो युक्ति है वही यहां भी समझनी चाहिए किन्तु यहां 'लम्बरेखा ७ अन्तर=० उपलब्ध होता है; अतः सिद्ध हुआ ।

अब रेवती में शराभाव क्यों होता है इसका निर्णय करते हैं ।

गोलद्वय(विषगोल और भगोल)के केन्द्रों से कदम्ब में और रेवती में जो रेखा लाये वे दोनों समानान्तर हैं अर्थात् कदम्बगत रेखाद्वय समानान्तर है तथा रेवतीगत रेखाद्वय भी समानान्तर है । इसलिए भूकेन्द्रलग्नकोण=स्थिरगोलीय या भगोलीय शरकोटि=दृष्टि-स्थान लग्न कोण=विषगोलीय शरकोटि, अतः इसको नवत्यंश में घटाने से शरचाप=० यह उपलब्ध हुआ इस लिए रेवती का शराभाव सिद्ध हुआ ।

अब प्रकृत विषय (अयनांश) का आनयन करते हैं ।

गोलद्वय केन्द्रों (भूकेन्द्र और दृष्टिस्थान) से ध्रुव में और रेवती में रेखायें लाये तब गोलद्वय केन्द्रलग्न कोणमान द्युज्याचाप बराबर होते हैं (क्योंकि गोलद्वय केन्द्रों से ध्रुवगत रेखाद्वय समानान्तर है तथा रेवतीगत रेखाद्वय भी समानान्तर है) इसलिए

$$६० - \text{रेवती द्युज्याचाप} = \text{रेवती क्रान्ति, तब } \frac{\text{त्रि} \times \text{ज्याक्रां}}{\text{ज्याजि}} = \text{ज्याभु, इसके चाप करने से}$$

रेवती का भुजांश=अयनांश, यह परम (परमायनांश)=२७° होता है ।

यहां प्रसङ्गवश आये हुए दोनों गोलों के लग्न, वित्रिभदृक्षेपचाप, अक्षांशचाप आदि की समत्व उपपत्ति स्वयमेव समझनी चाहिए ।

अब ग्रहों की पूर्वाभिमुखगति क्यों है इसका निर्णय करते हैं ।

प्रथमपद में ग्रह के रहने से उनकी तात्कालिक क्रान्ति की वृद्धि, द्वितीयपद में ह्रास (क्षोणत्व) तृतीयपद में प्रथमपद की तरह और चतुर्थपद में द्वितीयपद की तरह स्थिति वेव से देखते हैं । इसलिए ग्रहों की पूर्वाभिमुख गति है यह सिद्ध हुआ । और ग्रहों की भरण-पूर्ति बहुत दिनों में होती है तथा प्रवह की भरणपूर्ति एक ही दिन में होती है इसलिए प्रवहगति की अपेक्षा ग्रहगति की अल्पता भी सिद्ध हुई ।

अब ग्रहपिण्डों में गोलत्व है या नहीं और ग्रहों की स्थिति ऊर्ध्वाधर क्रम से क्यों है इनके लिए विचार करते हैं ।

एक गोल को कहीं पर रखकर दृष्टिस्थान में मूल (जड़) मिलित समान यष्टित्रय को इस तरह रखना चाहिए जिस से दृष्टिसूत्र सब गोल के स्पर्शकारक (याने गोल स्पर्शरेखायें) हो और वे दृश्यवृत्ताधार समसूची कर्णागत हो । यष्टियों के अग्रों में परस्पर रेखा करने से जो त्रिभुज बनता है उसके ऊपर जो वृत्त होता है उसका धरातल धावारवृत्त धरातल के समानान्तर है और पूर्वकथित समसूची के कर्णाग्रों में जाता है ।

परस्पर समयष्टित्रयाग्रागरेखाजनितत्रिभुजोपरिगत वृत्तकेन्द्र में दृष्टिस्थान से जा दृष्टिसूत्र आवेगा उसको बढ़ाने से आधार वृत्त केन्द्रगत भी होता है ये सब गोल ही धर्म है क्योंकि ये सब बातें गोलात्मक पदार्थ ही में हो सकती हैं। आचार्य ग्रहपिण्डों में गोलत्व स्वीकार कर पूर्व-कथित गोलीय धर्म देखते हैं इसलिए ग्रहपिण्डों में गोलत्व सिद्ध हुआ। वेध से ग्रहबिम्बीय कर्णज्ञान कैसे होता है इसे इसी ग्रन्थ में मङ्गलगुरु और शनि की शीघ्रोच्चोपपत्ति स्थल में देखना चाहिए। सब ग्रहों के बिम्बीय कर्णमान अनुल्य उपलब्ध हुए इसीलिए ग्रहों के कक्षानिवेश ऊर्ध्वाधर क्रम से (जिस ग्रह का कर्णमान जिस दूसरे ग्रह के कर्णमान से अधिक उपलब्ध हुआ उसकी कक्षा उस दूसरे ग्रह की कक्षा से उपरिगत हुई इसके अनुसार) चन्द्र, बुध, शुक्र, रवि, कुज, गुरु, शनि और नक्षत्रों की कक्षायें चन्द्र से उपरिक्रम से सब आचार्यों ने अपने-अपने सिद्धान्त ग्रन्थों में लिखी हैं।

‘सहग्रहेः’ इसकी युक्ति।

भूगर्भ से दृष्टिज्या व्यासार्ध से जो गोल होता है, वह भगोल है। ध्रुवसूत्र रूप यष्टी में बन्धे हुए भचक्र और भगोल के साथ-साथ आने-जाने के कारण उनसे मिले हुए मन्दगोल और शीघ्रगोल (जो ग्रहों के आधार गोल हैं) के भी भ्रमणादि उनके साथ ही होते हैं यह सिद्ध हुआ ॥—

इन उपपत्तियों से ‘ध्रुवताराप्रतिबद्धज्योतिश्चक्रं’ इत्यादि आचार्योंक्त सब सिद्ध हुआ।

ध्रुवसूत्रयष्टी के आधार पर पश्चिमाभिमुख भचक्र भ्रमण होता है। उस (ध्रुवयष्टी) के मध्य में ब्रह्मा ने कदम्बसूत्र इस तरह बांध दिया जिससे वह कदम्बसूत्र भचक्र के पश्चिमाभिमुख भ्रमण में विघ्न नहीं करते हुए ब्रह्मा के हाथ के आघात से उत्पन्न भ्रमण में भचक्र के पृष्ठ में कदम्ब स्थान में खचित (जड़ा हुआ) होकर स्थिर हो इसलिए ध्रुवसूत्र ध्रुवस्थान से कथितवेग (गति) की समाप्ति तक पूर्व और पश्चिम तरफ २७° भ्रंश पर्यन्त भचक्रगुण्ड को घिसता है अतः ध्रुवतारा स्थिर नहीं है केवल ध्रुवस्थान ही स्थिर है यह सिद्ध हुआ, इसलिए ‘तदन्ततारे च तथा ध्रुवत्वे’ यह भास्करोक्त ‘ध्रुवतारां स्थिरां ग्रन्थे मन्यन्ते ते कुबुद्धयः’ यह कमलाकरोक्त भी युक्तिसङ्गत है।

राश्यंशकलाविलिप्ताः' इत्यनेन सिद्धान्तशेखरे श्रीपतिना च 'एवं चक्रभ्रंशलिप्ता-
विलिप्तास्तुल्याः क्षेत्रेऽनेहसाब्दादिकेनेत्या'दिना ब्रह्मगुप्तोक्तानुरूपमेव कथ्यते,
किन्तु 'अक्षणेनिमेषः कथितो निमेषस्त्रिंशद्विभागोऽस्य च तत्परा स्यादित्यादिना
श्रीपतिना, योऽक्षणीनिमेषस्य खरामभागः स तत्परस्तच्छतभाग उक्त' इत्यादिना
भास्करेण च ब्रह्मगुप्तोक्तादधिकं कथ्यते, वटेश्वरसिद्धान्ते निमेषादेर्या परिमितयः
परिभाषितास्ततो भिन्ना एवोपर्युक्ताचार्यकथिताः । सर्वान् विलोक्य विवेचका
गाणितिका विवेचयन्ति ॥ ५-६ ॥

अब कालमानों की विभागकल्पना को कहते हैं ।

हि. भा.—छह असु को एक नाक्षत्री विघटिका (पल) होती है, साठ पल की एक घटी (दण्ड) होती है । साठ घटी का एक दिन होता है, तीस दिनों का एक मास होता है । बारह मासों का एक वर्ष होता है । पल, दण्ड, दिन, मास, और वर्ष इन्हीं के बराबर क्षेत्रीय (कक्षा) विभाग विकला, कला, अंश, राशि और भरण हैं अर्थात् जैसे एक वर्ष का विभाग मास, दिन आदि हैं वैसे ही एक भरण का विभाग राशि, अंश आदि हैं । इनके स्पष्टीकरण के लिए नीचे लिखकर दिखलाता हूँ ।

इन के बराबर ही क्षेत्रीय (कक्षा) विभाग होता है । जैसे—

६ असु = १ पल	विकला —
६० पल = १ घटी	६० विकला = १ कला
६० घटी = १ दिन	६० कला = १ अंश
३० दिन = १ मास	३० अंश = १२ राशि
१२ मास = १ वर्ष	१२ राशि = १ भरण

सिद्धान्तशिरोमणि में भास्कराचार्य 'क्षेत्रे समाद्येन समा विभागाः स्युश्चक्रराश्यंशकला-विलिप्ताः' इससे तथा सिद्धान्तशेखर में श्रीपति 'एवं चक्रांशलिप्ता विलिप्तास्तुल्याः क्षेत्रेऽनेह-साऽब्दादिकेन, इससे ब्रह्मगुप्तोक्त के अनुरूप ही कहते हैं लेकिन, 'अक्षणोन्निमेषः कथितो निमेषस्त्रिंशद्विभागोऽस्य च तत्परा स्यात्' इत्यादि से श्रीपति तथा 'योऽक्षणोन्निमेषस्य खरामभागः स तत्परस्तच्छतभाग उक्ता' इत्यादि से भास्कराचार्य भी ब्रह्मगुप्तोक्त से अधिक कहते हैं । वटेश्वरसिद्धान्त में वटेश्वराचार्य निमेष आदि कालप्रमाण की जो परिभाषायें करते हैं वे श्रीपत्यादिकथित उनके मानों की परिभाषाओं से भिन्न ही हैं । इन सब बातों को देखकर विवेचक ज्योतिषी लोग विचार करें इति ॥५-६॥

चतुर्युगसंख्या युगचरणमानानि च प्रदर्शयन्नामभ्यामाह ।

खचतुष्टयरदवेदा ४३२०००० रविवर्षाणां चतुर्युगं भवति ।

संध्यासंध्यांशैः सह चत्वारि पृथक् कृतादीनि ॥ ७ ॥

युगवशभागे गुणितः कृतं १७२०००० चतुर्भिस्त्रिभिर्गुण १२६६००० स्त्रेता ।

द्विगुणो ८६४००० द्वारपरमेकेन सङ्गुणः ४३२००० कलियुगं भवति ॥ ८ ॥

वा. भा.—रविवर्षाणां खचतुष्टयरदवेदसंख्यया चतुर्युगं भवति । खचतुष्ट-यरदवेदाश्चाथ प्रदक्षिणेन स्थाप्यमानाः त्रिचत्वारिंशल्लक्षाणि विंशतिश्च सहस्राणि भवन्ति ४३२०००० संध्यासंध्यांशैः सहेति येयं चतुर्युगसंख्या मयाभिहितेषा संध्या-संध्यांशैश्च सह । संध्या च कृतादीनां स्वद्वादशभागतुल्या संध्यांशश्च तावानेव मानवे

धर्मशास्त्रे पठ्यते । चत्वारः पृथक् पृथक् । कृतत्रेताद्वापर-कलियुगानि च तत्रैव पठ्यन्ते इति चेह यथा भवन्ति तथार्यमाह ।

युगशब्देन चतुर्युगमुच्यते, तेनायमर्थः युगदशभागः खत्रिरदवेदाश्चतुस्थानस्थाः क्रमेण चतुर्भिस्त्रिद्व्येकगुणाः सन्तश्चत्वारि पृथक् कृतादीनि मानानि भवन्ति । तद्यथा वसुयमनगेन्दवः, रसनवनेत्रचन्द्राः, कृतषड्वसवोः द्वित्रिवेदाः सर्वे सहस्राध्नाः १७२८००० कृतमानम्, १२९६००० त्रेतामानम् ८६४००० द्वापरमानम्, ४३२००० कलियुगमानम् । एतावती वर्षसंख्या सौरेण मानेन कृतयुगादीनां भवति ।

iv. भा.—रविवर्षाणां (सौरवर्षाणां) खचतुष्टयरदवेदाः ४३२०००० चतुर्युगं (महायुगं) भवति, सन्ध्यासन्ध्यांशैः सह कृतादीनि (सत्ययुगादीनि) पृथक् चत्वारि युगचरणमानानि भवन्ति, युगदशभागः ४३२००० चतुर्भिर्गुणितस्तदा कृतं (सत्ययुगचरणमानं) १७२८००० भवति, त्रिभिर्गुणितः १२९६००० त्रेतायुगचरणमानम् । द्विगुणितः ८६४००० द्वापरयुगचरणमानं भवति । एकगुणितः ४३२००० कलियुगचरणमानं भवति । अत्रैतदुक्तं भवति युगचरणद्वादशांशसमस्तसन्ध्या, सा चरणदौ भवति तावानेव सन्ध्यांशः स च युगचरणान्ते भवति, सन्ध्यासन्ध्यांशैः सह एते युगचरणाः कथिताः ।

कृतादौ सन्ध्यावर्षाणि = $\frac{\text{कृतयुगच}}{१२} = \frac{१७२८०००}{१२} = १४४०००$, कृतान्ते सन्ध्यांशः = १४४०००, एवं त्रेतादौ सन्ध्यावर्षाणि = $\frac{१२९६०००}{१२} = १०८०००$, त्रेतान्ते सन्ध्यांशः १०८०००, द्वापरादौ सन्ध्यावर्षाणि = $\frac{८६४०००}{१२} = ७२०००$, द्वापरान्ते सन्ध्यांशः = ७२०००, कलियुगचरणान्ते सन्ध्या = $\frac{४३२०००}{१२} = ३६०००$, कलियुगचरणान्ते सन्ध्यांशः = ३६०००, चतुर्णां युगचरणानां योगः पूर्वोक्तयुगमानं भवतीति ॥६-८॥

अब युगमान कहते हैं ।

हि. भा.—४३२०००० इतने सौर वर्ष का एक युग होता है । सन्ध्या और सन्ध्यांश सहित पृथक् सत्ययुगादि चार युग चरण होते हैं । युग के दशमांश को चार से गुणने से कृतयुगचरणमान १७२८००० होता है, तीन से गुणने से त्रेतायुगचरण १२९६००० होता है । दो से गुणने से द्वापरयुगचरण ८६४००० होता है, और एक से गुणने से कलियुगचरण ४३२००० होता है ।

युगचरणों का द्वादशांश अपनी-अपनी सन्ध्या और सन्ध्यांश होता है अर्थात् युगचरण के आदि में सन्ध्या और उत्तरे ही युगचरण के अन्त में सन्ध्यांश होता है । सन्ध्या और सन्ध्यांश से सहित पूर्वोक्त युगचरण मान होता है ।

कृतादि में सन्ध्यावर्ष $\frac{१७२८०००}{१२} = १४४०००$ कृतान्त में सन्ध्यांश = १४४०००, त्रेतादि में सन्ध्यावर्ष = $\frac{१२९६०००}{१२} = १०८०००$, में सन्ध्यांश = १०८०००, द्वापरादि में सन्ध्यावर्ष = $\frac{८६४०००}{१२} = ७२०००$, द्वापरान्त में सन्ध्यांश = ७२०००, कलियुगचरणादि

सन्ध्य वर्षं = $४३३\frac{१}{२} = ३६०००$, कलियुगचरणान्त में सन्ध्यांश = ३६००, चारों युगचरणों का योग पूर्वकथित युगमान होता है। इति ॥७-८॥

इदानीमार्यभटोक्तानां कृतादीनां यानि वर्षसंख्याप्रमाणानि तेषां स्मृतिविरोधाद् दूषणमाह ।

युगपादानार्यभटश्चत्वारि समानि कृतयुगादीनि ।

वा. भा. युगपदेनात्र चतुर्युगमुच्यते । तेन युगस्य पादा युगपादाः युगचतुर्भागा इत्यर्थः । तावत् एव युगपादान् आर्यभटो यदभिहितवान् चत्वारि युगानि कृत-युगादीनि तदसदुक्तं भवति । यदार्यभटेनोक्तं दश गीतिकासु 'गतास्ते च मनुयुग(ख) कल्पादेर्युगपाद' इति तदयुक्तम् । यस्मात् तेषां कृतादियुगानामार्यभटोक्तानां स्मृत्युक्तत्वादियुगेन तुल्यमेकमपि न भवत्यत्र च भगवान्मनुः "चत्वार्याहुः सहस्राणि वर्षाणि च कृतं युगम् । तस्य तावच्छती संध्या संध्यांशश्च तथाविधः ।" एतावद्विव्येन मानेन, तद्यथा दिव्यवर्षः कृतयुगपरिमाणम् ४००० अस्य संध्या ४०० संध्यांशश्च ४०० एकत्र ८०० एतत्संध्यासंध्यांशैः सह कृतयुगपरिमाणम् । इतरेषां त्रेतादीनां त्रेता ३००० सन्ध्या ३०० संध्यांशः ३०० द्वापरः २००० संध्या २०० संध्यांशश्च २०० कलिः १००० संध्या १०० संध्यांशः १००, एकत्र त्रेता ३६०० । द्वापरः २४०० कलिः १२०० एतानि षष्टिशतत्रयेण गुणितानि सौरमानेन कृतादीनां वर्षाणि भवन्ति, ब्रह्मगुप्तोक्तयुगानां तुल्यानि १७२८००० । १२६६००० । ८६४००० । ४३२००० नार्यभटोक्तसममपि । पौलिशे दिव्येन मानेन कृतादीनां प्रमाणाब्दाः "अष्टाचत्वारिंशत्पादविहीनाः क्रमात्कृतादीनाम् । अब्दास्ते शतगुणिता ग्रहतुल्य-युगं तदेकत्वम्" इति पौलिशसिद्धान्ते द्रष्टव्यम् ॥

वि. भा.—आर्यभटः चत्वारि समानि (तुल्यानि) कृतयुगादीनि युगपादान् महायुगचतुर्थांशमितान् युगचरणान् यदभिहितवान् (यत्कथितवान्) तेषां युग-पादानां (युगचरणानां) मानमध्ये एकमपि स्मृत्युक्तसमानं (स्मृतिकथितसदृशं) न, स्मृतिकथितयुगचरणमानानि समानानि न सन्ति तस्मादार्यभटकथितानि तुल्य-युगचरणमानानि स्मृतिविरुद्धानि तेनोपेक्ष्याणीत्यर्थः । युगचरणसम्बन्धे आर्यभट-वाक्यम् 'युगपादाः ग ३ च'; इति । तथा—

अष्टाचत्वारिंशत् पादविहीना क्रमात्कृतादीनाम् । अब्दास्ते शतगुणिता ग्रहतुल्ययुगं तदेकत्वम् । इति पौलिशसिद्धान्तोक्तं दिव्यमानेन कृतादियुगचरण-वर्षमानं स्मृत्युक्तसमानमवलोक्यते । नहि केनापि स्मृत्युक्तवचनेन पुराणोक्तवचनेन चार्य-भटभतस्य पुष्टिर्भवत्यतस्तन्मतं न शोभनम् ज्योतिषसिद्धान्तकारेषु केवलं वटेश्वर-सिद्धान्तकारः (वटेश्वरः) आर्यभटस्येदं मतं स्वीकरोत्येतदर्थं किमपि प्रबलं प्रमाणं नोपस्थापयत्यतस्तन्मतमपि न शोभनमिति ॥६॥

अब आर्यभटोक्त युगचरणमान को कहते हैं, खण्डन भी करते हैं ।

हि. भा.—आर्यभट ने चार बराबर कृतादि युगचरणों (महायुग के चतुर्थांशतुल्य) को जो कहा है, उन युगचरणों में एक भी स्मृतिकथित युगचरण के बराबर नहीं है, स्मृतिकथित युगचरणमान सब बराबर नहीं हैं । इसलिए आर्यभटोक्त तुल्य युगचरणमान स्मृति के विरुद्ध होने से उपेक्षणीय (त्याज्य) है, युगचरण के विषय में आर्यभटोक्त वाक्य है 'युगपादाः ग३च' तथा 'अष्टाचत्वारिंशत् पादविहीना क्रमात् कृतादीनाम् । अब्दास्ते शतगुणिता ग्रहतुल्ययुगं तदेकत्वम्' इस पौलिश-सिद्धान्तोक्त दिव्यमान से कृतादि युगचरणवर्षमान स्मृतिकथित वर्ष के बराबर ही देखने में आते हैं, आर्यभटमत की पुष्टि किसी स्मृतिवचन से या पुराणोक्त वचन से नहीं होती है, इसलिए उनका मत ठीक नहीं है । वटेश्वरसिद्धान्त में वटेश्वराचार्य ने आर्यभट के इस मत को स्वीकार किया है परन्तु विरोध में स्मृतिकारादियों के मत रहते हुए भी कोई प्रबल प्रमाण नहीं उपस्थापित किया है इसलिए उनका मत भी ठीक नहीं है ॥६॥

इदानीं मनुप्रमाणानि कल्पप्रमाणं चाह ।

मनुरेकसप्ततियुगः कल्पो मनवश्चतुर्दश मनूनाम् ।

आद्यन्तरान्तसन्धिषु कृतकालोऽस्माद्युगसहस्रम् ॥ १०॥

वा. भा.—मनुस्तावदेकसप्ततियुगैः । युगग्रहणेन चतुर्युगमुच्यते । एकसप्तति-चतुर्युगैः मन्वन्तरं भवतीत्यर्थः । कल्पस्तु मनवश्चतुर्दश, यद्येवं न तर्हि चतुर्युग-सहस्रं कल्प इत्याशङ्क्याह, मनूनामाद्यन्तरान्तसन्धिषु कृतकाल इति । मनूनामादि-सन्धिश्चांतरसन्धिश्चान्तसन्धिश्च ते भवन्त्याद्यन्तरान्तसंघयः चतुर्दशानां मनूनां पञ्चदश सन्धयो भवन्तीत्यर्थः । तेषु कृतयुगतुल्यः काल एकैकस्मिन् संधौ कृतयुग-तुल्यानि वर्षाणि भवन्तीति यावत् । अस्माद्धेतोश्चतुर्युगसहस्रेण स्मृतिषु कल्पोऽभिहितः । तद्यथा मन्वन्तरं चतुर्युगानि एतानि चतुर्दशगुणानि वेदनवनन्दा ६६४ कृताब्दाः १७२८००० पंचदश गुणा २५६२०००० चतुर्युगप्रमाणैरेतैः ४३२०००० विभज्यावाप्तं ६ । इदं पूर्ववन्त्येतेषु ६६४ एषु संयोज्य जातं सहस्रम् १००० यैस्तु पुनरष्टोत्तरेण चतुर्युगसहस्रेण कल्प उक्तस्तैः स्मृतिविरोधः कृत इत्यर्थः । यतो भगवान्मनुः "दैविकानां युगानान्तु सहस्रपरिसंख्यया, ब्राह्म-मेकमहो ज्ञेयं तावती रात्रिरेव च" इति । तथा च व्यासमुनिः "सहस्रयुगपर्यन्त-महो ये ब्रह्मणो विदुः । रात्रि युगसहस्रांतां तेऽहोरात्र-विदो जना" इति ॥१०॥

वि. भा.—एकसप्ततियुगैः मनुक्तः । चतुर्दश मनवः कल्पः (अथच्चतुर्दशम-नूनामेकः कल्पः) भवति, मनूनामाद्यमध्यावसानसन्धिषु कृतकालः (कृतयुगसमान-कालः) अस्मात् कारणाद्युगसहस्रं कल्प इति ॥

अत्रोपपत्तिः—युगसहस्रं कल्पः कथं भवतीति प्रदर्शयते—

एकसप्ततियुगानामेको मनुः=७१ युगाः, परं कल्पे चतुर्दश मनवोऽन्तः १४ मनु=७१यु×१४=९९४ युः परं मनुनामाद्यमध्यावसानसन्धिषु कृतकाल इत्युक्तेः

$$\begin{array}{l|l} \text{सन्ध्यासन्ध्यांशः} = \text{कृतयुगचरण} \times १५ & \text{चतुर्दश मनुषु सन्धयः} = १५ \\ = \frac{४\text{युग} \times १५}{१०} = ६यु & \text{युगे धर्मचरणाः} = १० \\ & \text{ततः} = \frac{४ \times \text{युग}}{१०} = \text{कृतयुग} \end{array}$$

ततः १४ मनु + मनुसन्ध्यासन्ध्यांश = ९९४यु + ६यु = १०००यु = १ कल्पः = ब्रह्मदिनम् ।

एतावता 'चतुर्युगसहस्रेण ब्रह्मणो दिनमुच्यते' इति पुराणोक्तं युगसहस्रं कल्प इति ब्रह्मगुप्तोक्तं चाप्युपपद्यते । सूर्यसिद्धान्ते सूर्यसिद्धान्तकारेण 'इत्थं युगसहस्रेण भूतसंहारकारकः । कल्पो ब्राह्ममहः प्रोक्त' मित्यनेन, भास्करेणापि स्याद्युगानां सहस्रं दिनं वेधसः सोऽपि कल्पः' इत्यनेन तदेव कथ्यते इति ॥ १० ॥

अब मनुमान और कल्पमान को कहते हैं ।

हि. भा.—इकहत्तर युगों का एक मनु होता है । चौदह मनु कल्प है, मनुओं के आदि, मध्य और अन्त में सन्धियां कृतकाल के बराबर हैं इस कारण एक हजार युगों का कल्प होता है ॥ १० ॥

एक हजार युगों का कल्प क्यों होता है इसकी उपपत्ति ।

इकहत्तर युगों का एक मनु होता है परन्तु कल्प में चौदह मनु हैं अतः १४ मनु = ७१ यु × १४ = ९९४ यु.

लेकिन मनुओं के आदि, मध्य और अन्त में कृतयुग के बराबर सन्धि है इसलिए चौदह मनुसम्बन्धी सन्ध्यासन्ध्यांश = कृतयुग × १५ अतः चौदह मनुसम्बन्धिनी सन्धि = १५

$$= \frac{४\text{युग} \times १५}{१०} = ६यु$$

युग में धर्मचरण = १०, कृतयुग में धर्मचरण = ४

इसलिए $\frac{४ \times \text{युग}}{१०} = \text{कृतयुग}$

अतः १४ मनु + मनुसन्ध्यासन्ध्यांश = ९९४यु + ६यु = १०००यु = १ कल्प = ब्रह्मदिन, इससे 'चतुर्युगसहस्रेण ब्रह्मणो दिनमुच्यते' यह पुराणोक्त और 'युगसहस्रम्' यह ब्रह्मगुप्तोक्त भी सिद्ध हो गया । सूर्यसिद्धान्त में सूर्यसिद्धान्तकार 'इत्थं युगसहस्रेण भूतसंहारकारकः । कल्पो ब्राह्ममहः प्रोक्तम्,' इससे सिद्धान्तशिरोमणि में भास्कराचार्य भी 'स्याद्युगानां सहस्रं दिनं वेधसः सोऽपि कल्प' इससे उसी विषय को कहते हैं ॥ १० ॥

इदानीं कल्पे विशेषं प्रतिपादयति ।

ग्राह्यन्तरान्तसन्धिषु कल्पमनूनां कृताब्दसमकालम् ।

नेच्छन्ति ये षड्वनं तेषां कल्पो युगसहस्रम् ४२६४००००० ॥११॥

वा. भा.—कल्पे मनवः कल्पमनवः तेषामाद्यन्तरान्तसन्धिषु कृतयुगतुल्यः कालो यैर्नेप्सितस्तेषां कल्पश्चतुर्युगशतैः नवभिश्चतुर्नवत्यधिकैः भवतीति किमत्रोच्यते । प्रागार्या व्याख्यानेनैव येषामार्या गतार्थेति ।

वि. भा.—ये कल्पमनूनां (चतुर्दशमितानां) कृताब्दसमकालं (कृतयुगवर्षं) ग्राह्यन्तरान्तेषु (ग्रादिमध्यावसानेषु) सन्धि नेच्छन्ति तेषां मते कल्पः षड्वनं युगसहस्रं भवति ।

एकसप्ततियुगैरेको मनुर्भवति, परं कल्पे चतुर्दश मनवोऽतः १४ मनु ७१यु × १४ = ६६४यु. अत्र चतुर्दशमनुसम्बन्धिसंख्यासंख्यांशमानं योज्यते तदा वस्तुतः कल्पप्रमाणं भवति, परं ये मनुसम्बन्धिसंख्यासंख्यांशमानं न गृह्णन्ति तन्मते तु ६६४यु. = कल्पः ॥११॥

अब कल्प के सम्बन्ध में विशेष कहते हैं ।

हि. भा.—ग्राचार्य कल्पमनु (चतुर्दश-संख्यक) सम्बन्धी आदि, मध्य और अन्त में सन्धि को कृताब्द (सप्तयुगवर्ष) के बराबर नहीं मानते हैं, उनके मत में कल्पप्रमाण छः घटा हुआ एक हजार युग (६६४ युग) होता है ॥११॥

इकहत्तर युगों का एक मनु होता है, लेकिन कल्प में चौदह मनु हैं इसलिए. १४ मनु = १४ × ७१यु = ६६४यु, इसमें मनुसम्बन्धी संख्यासंख्यांश जोड़ने ही से वास्तवकल्प प्रमाण हो सकता है, जो उनके मान नहीं लेते हैं उनके मत में ६६४ यु = कल्प पर यह ठीक नहीं है ॥११॥

इदानीं कल्पसम्बन्धे आर्यभटमत्तं प्रदर्शयन्नाह

मनुसन्धि युगमिच्छः आर्यभटस्तन्मनुर्यतः श्लयुगः ।

कल्पश्चतुर्गुणानां सहस्रमष्टाधिकं तस्य ४३५४५६०००० ॥ १२ ॥

वा. भा.—मनोः सन्धिः मनुसन्धिः । सन्धिमिच्छत्यार्यभटः युगतुल्यं प्रायेण । यतः तन्मनुः श्लयुगः तस्य मनुस्तन्मनुः स च संख्या निर्युगानि यत्र.....सम.....युग.....तद्वं.....सुकननुयु.....द्वास.....तस्य मन्वन्तरं भवतीत्यर्थः । एवं चतुर्युगानां सहस्रमष्टाधिकं तस्य कल्पः । तथा चाष्टशते अष्टोत्तर-सहस्रं ब्राह्मो दिवसा ग्रहयुगानामिति ॥ यथा कुडव-प्रस्थ-द्रोणाद्यैः मेघो राशिः परिच्छिद्यते एवं युगमन्वन्तरकल्पैः काल इति स्मृतिषु पठ्यते । तथाचार्यश्रीवेण-निबद्धे रोमकसिद्धान्ते न पठितः ।

वि. भा.—आर्यभटो युगं (युगतुल्यं) मनुसन्धिमिच्छति, यतस्तत् (तस्याऽय-
भटस्य) मनुः स्वयुगोऽर्थाद् द्विसप्ततियुगैर्भवति अतस्तस्याऽर्यभटस्य मते चतुर्युगानां
(महायुगानां) अष्टाधिकं सहस्रं (१००८) कल्पः (ब्रह्मदिनं) भवतीति ॥ १२ ॥

अत्रोपपत्तिः ।

वर्गाक्षराणि वर्गे इत्याचार्यभटोक्तेः श=७०, ख=२ एतयोर्योगः=७२,
ब्रह्मगुप्तादिभिरेकसप्ततियुगैरेको मनुः कथ्यते, आर्यभटेन द्विसप्ततियुगैः
कथ्यते । तेन त-मते युगसम एव मनुसन्धिरिति स्पष्टं प्रतीयते । तन्मतेनापि कल्प-
मानम्=१४ मनु=१४×७२ युग=१००८ युग=कल्पः, एतेन 'कल्पश्चतुर्युगानां
सहस्रमष्टाधिकं तस्ये'ति ब्रह्मगुप्तोक्तमुपपद्यते ।

दशगीतिकायाम् । “काहो मनवो ढ १४ मनुयुगं स्व ७२ गतास्ते च ६
मनुयुगं छ्ना २७ च । कल्पादेर्युगपादा ग३ च गुरुदिवसाच्च भारतात्पूर्वम्” इति ।

कालक्रियापादे च “दिव्यं वर्षसहस्रं ग्रहसामान्यं युगं द्विषट्कगुणम् । अष्टो-
त्तरं सहस्रं ब्राह्मो दिवसो ग्रहयुगानाम् ॥” इति च आर्यभटोक्तमस्ति । केवलमार्य-
भटेन ब्रह्मगुप्तमतविरोधिनाऽर्यभटमताश्रयिणा वटेश्वराचार्येण च द्विसप्ततियुगैरेकः
कल्पो भवतीति कथ्यते परं तत्समर्थनमन्येज्यौतिषाचार्यैः स्मृतिकारैः पुराणैश्च
न कृतं, तेन तन्मतं कथं शोभनमिति सुधियो विभावयन्त्विति ॥ १२ ॥

अब आर्यभटोक्त कल्पमान को कहते हैं

हि. भा.—आर्यभट भी युगतुल्य मनुसन्धि स्वीकार करते हैं क्योंकि उनके मत में
एक मनु स्व युग (७२ युग) बहत्तर युगों के होते हैं और एक हजार आठ युगों (कृतयुग
त्रेता, द्वापर और कलियुगों के योग=युग) के कल्प (ब्रह्मदिन) होता है ॥ १२ ॥

उपपत्ति

ब्रह्मगुप्तादि आचार्य इकहत्तर युगों के एक मनु कहते हैं, आर्यभट बहत्तर युगों को
एक मनु कहते हैं इसलिए उनके मत में युगसमान ही मनुसन्धि है यह स्पष्ट प्रतीत होता है ।
उनके मत में भी कल्प=१४ मनु=१४×७२युग=१००८ युग= ब्रह्मदिन, इससे 'कल्प-
श्चतुर्युगानां सहस्रमष्टाधिकं तस्य' यह ब्रह्मगुप्तोक्त उपपन्न होता है ।

आर्यभट दशगीतिका में कहते हैं

“काहो मानवो ढ १४ मनुयुगं स्व ७२ गतास्ते च ६ मनुयुगं छ्ना ७२ च ।
कल्पादेर्युगपादा ग३ च गुरुदिवसाच्च भारतात्पूर्वम् ॥”

कालक्रियापाद में—

“दिव्यं वर्षसहस्रं ग्रहसामान्यं युगं द्विषट्कगुणम् । अष्टोत्तरं सहस्रं ब्राह्मो
दिवसो ग्रहयुगानाम् ॥” केवल आर्यभट और ब्रह्मगुप्त-मत विरोधी तथा आर्यभटमताश्रयी

वटेश्वराचार्य बहत्तर युगों का कल्पमान कहते हैं, लेकिन उनके मत का समर्थन अन्य किसी ज्योतिषाचार्य, स्मृतिकार तथा पुराणों ने नहीं किया है इसलिए उनका मत कैसे ठीक है इस बात का विवेचक लोग विचार करें ॥ १२ ॥

इदानीं रोमकसिद्धान्तमतं खण्डयति ।

युगमन्वन्तर कल्पाः कालपरिच्छेदकाः स्मृतावुक्ताः ।

यस्मान्न रोमके ते स्मृतिबाह्यो रोमकस्तस्मात् ॥ १३ ॥

वि. भा.—यस्मात् कारणात्स्मृतौ (वेदार्थप्रतिपादके ग्रन्थे) युगमन्वन्तर-कल्पाः (युगमन्वन्तरादयः) कालपरिच्छेदकाः (समयविभाजकाः) उक्ताः (कथिताः) अन्यथाऽनाद्यनन्तव्यापककालेन मानवानामेकमपि व्यवहारकार्यं न चलेत् । रोमके (रोमकसिद्धान्ते, ते (युगमन्वन्तरादयो) न सन्त्यर्थात्तेषां तेषां नामोल्लेखा न सन्ति तस्मात्कारणाद्रोमकः स्मृतिबाह्योऽतोऽत्र रोमकसिद्धान्तस्त्याज्य इति ॥ वस्तुतो ज्योतिषसिद्धान्तग्रन्थेषु युगमन्वन्तरकल्पानां ग्रहादिसाधनार्थं कीदृशं प्राधान्यमिति तत्साधका एव ज्ञातुं शक्नुवन्ति । तान् विना सकलं ज्योतिषशास्त्रं निरर्थकमेव भवेत् । अतो रोमकसिद्धान्ते तच्चर्चाकरणेन कीदृश्यस्त्रुटयः कृतास्त-त्सिद्धान्तकर्त्रेति मन्दमतयोऽपि ज्ञातुं शक्यन्तीति ॥ १३ ॥

अब रोमकसिद्धान्त मत का खण्डन करते हैं ।

हि. भा.—जिस कारण से वेदार्थ के प्रतिपादन करने वाले स्मृतिग्रन्थों में युग-मन्वन्तर और कल्प को काल (समय) का परिच्छेदक (विभाजक) कहा गया है अर्थात् इन्हीं युग-मन्वन्तरादियों के द्वारा विभक्त अनाद्यनन्त व्यापक काल से मानवों के सब व्यवहार चलते हैं, यदि ऐसा नहीं होता तो अविभक्त व्यापककाल से एक भी कार्य होना असम्भव है इसलिए पूर्वोक्त विषयों के उल्लेख स्मृतिकारों ने अत्यावश्यक समझ कर किये हैं । रोमकसिद्धान्त में इन सब की चर्चा भी नहीं की गई है इसलिए वह सिद्धान्त स्मृतिबाह्य है अर्थात् स्मृतिशास्त्रों से बहिर्भूत है इसलिए वह त्याज्य है । वस्तुतः ज्योतिषसिद्धान्त में युग-मन्वन्तरादियों की ग्रहादि साधनार्थं कैसी प्रधानता है यह विषय ग्रहादि साधन करने वाले ही जान सकते हैं । बिना उनके सम्पूर्ण ज्योतिष-शास्त्र निरर्थक है इसलिए रोमक सिद्धान्त में उनकी चर्चा न करके बहुत बड़ी त्रुटि की गई है, इस बात को अल्पज्ञ भी समझ सकते हैं ॥ १३ ॥

अथैषां पातभगणोपपत्तिः

अथैषां वेधगोलीयशरज्ञानतो भगोलीयशरान् ज्ञात्वा तदभावो यत्र भवेत्तत्र
गणितागतान् तान् मन्दस्पष्टग्रहान् द्वादशराशिभ्यः शुद्धान् कृत्वा पातो ज्ञेयः ।
द्वितीयपर्ययेऽप्येवं तत्पातो ज्ञेयस्तदन्तरैस्तद्दिनान्तरैश्च पूर्ववत्तत्पातभगणा
भवन्तीति ॥१३॥

रवि, बुध और शुक्र की भगणोपपत्ति

‘रविभगणा रव्यब्दाः’ इस आचार्योक्ति से कल्प में जितने रविभगण होते हैं उतने
ही सौर वर्षमान होते हैं, लेकिन कल्पवर्षप्रमाण विदित है इसलिए तत्तुल्य
कल्परविभगण मान भी विदित हो गया, बुध और शुक्र के उदयलक्षण में रवि
के उदयकाल और अस्तकाल में रवि और बुध के अन्तरांश तथा रवि और शुक्र
के अन्तरांश भी प्रत्येक दिन यन्त्रद्वारा जानने चाहिएँ। वे अन्तरांश तीन राशि से
अल्प ही आता है। बराहमिहिराचार्य भी ‘बृहज्जातक में पूर्वाचार्योक्त वज्रादि योगों के
खण्डन में ‘पूर्वशास्त्रानुसारेण मया वज्रादयः कृताः । चतुर्थे भवने सूर्याज्जसितौ भवतः
कथम् ।’ इत्यादि से रवि के साथ बुध और शुक्र का अन्तर अल्प ही होता है, ऐसा कहते
हैं। इसलिए रवि के अतिनिकट (समीप) रहने के कारण कभी आगे कभी पीछे उनके
नीकर की तरह बुध और शुक्र जाते हुए देखे जाते हैं। इसी कारण से बुध और शुक्र के
कल्पभगण कल्परविभगण के बराबर ही आचार्यों ने स्वीकार किये हैं ।

चन्द्रभगण की उपपत्ति

ग्रहवेध के लिए हर तरह से उपयुक्त स्थान में वेधालय बनाना चाहिए ।
उसमें नाडीवृत्त, क्रान्तिवृत्त, कदम्बप्रोतवृत्त आदि वृत्तों से युक्त एक गोल यन्त्र बनाना
चाहिए । क्रान्तिवृत्त में भगणांश ३६० और राशि-अंश-कला आदि अङ्कित करना
तथा नाडीवृत्त में दण्ड, पल आदि चिह्नित करना, किन्हीं दो आधारों पर तथा केन्द्र-
गत नलिका से उस गोलयन्त्र को खूब दृढ़ कर, गोलकेन्द्र में ध्रुवाभिमुख (ध्रुव
की तरफ) दृष्टि को करके रात्रि में उस गोलकेन्द्रगत दृष्टि के द्वारा रेवती तारा को
देखने से गोलयन्त्रीय क्रान्ति वृत्त में जहाँ पर परिणत हुई वहीं पर मेषादि चिह्नित
करना । तथा गोल केन्द्रगत दृष्टि ही से चन्द्र के वेध करने से गोलयन्त्र में जहाँ
परिणत हुए उनके ऊपर गोलयन्त्रीय कदम्ब प्रोतवृत्त (वेधवृत्त) करने से वह वृत्त
(वेधवृत्त) गोलयन्त्रीय क्रान्तिवृत्त में जहाँ पर लगता है वही वेधागत स्पष्ट चन्द्र है ।
मेषादि से उनके जितने राश्यादिमान हैं वही राश्यादि स्पष्टचन्द्र है । इस तरह स्पष्ट-
चन्द्र का ज्ञान हो गया, इसी तरह द्वितीय दिन में भी स्पष्टचन्द्र का ज्ञान करना,

इन विदित स्पष्टचन्द्रद्वय से तथा विदित चन्द्रमन्दोच्च से 'स्फुटं ग्रहं मध्यखगं प्रकल्प्य कृत्वा फले मन्दचले यथोक्ते' इत्यादि से दोनों दिनों के मध्यम चन्द्र जान कर दोनों मध्यम चन्द्रों के अन्तर (चन्द्रमध्यमगति) जान लेना. इससे अनुपात करते हैं यदि एक दिन में यह चन्द्रमध्यम गति पाते हैं तो कल्प कुदिन में क्या इससे कल्प चन्द्रभगण मान आते हैं। लेकिन इस उपपत्ति में वेध द्वारा जो स्पष्टचन्द्र लिये गये हैं वे वेधगोलीय (हृग्गोलीय या भूपृष्ठस्थान में दृष्टिस्थान रखने से पृष्ठीय त्रिज्यागोलीय) हैं, लेकिन भूकेंद्रिक त्रिज्यागोलीय स्पष्टचन्द्र अपेक्षित है, इसलिए वेध-गोलीय स्पष्टचन्द्र और भूकेंद्रिक त्रिज्यागोलीय (भूगर्भगोलीय) स्पष्टचन्द्र का अन्तरानयन करके वेधगोलीय स्पष्टचन्द्र में उस अन्तर को संस्कार करना तब भूगर्भ-गोलीय स्पष्टचन्द्र होते हैं। इसी तरह वेधगोलीय द्वितीय दिन के स्पष्ट चन्द्र से गर्भगोलीय स्पष्ट चन्द्र ज्ञात करना, तब इन विदित भूगर्भगोलीय स्पष्टचन्द्रद्वय से 'स्फुटं ग्रहं मध्यखगं प्रकल्प्य' इत्यादि से दोनों दिनों के मध्यम चन्द्र ज्ञात कर अन्तर करने से एक-दिन-सम्बन्धित चन्द्र-मध्यमगति होती है इससे पूर्ववत् कल्पचन्द्रभगण ज्ञात करना।

उपर्युक्त उपपत्ति में वेधगोलीय स्पष्टचन्द्र से भूगर्भगोलीय स्पष्टचन्द्र ज्ञान का उल्लेख किया गया है परन्तु वह अवतरण रूप में कहा गया। अब यहाँ उस का साधनप्रकार लिखते हैं। यहाँ स्पष्टचन्द्र का प्रसङ्ग है इसलिए दोनों गोलीय (वेधगोलीय और भूगर्भगोलीय) स्पष्टचन्द्रों का अन्तरानयन करते हैं परन्तु जिस किसी वेधगोलीय स्पष्टग्रह से भूगर्भगोलीय स्पष्टग्रहज्ञान करना हो तो यही अधोलिखित उपपत्ति समझनी चाहिए। वेधगोल में दृष्टिवश परिणत चन्द्रबिम्ब के स्पष्टभोग चिह्न (परिणतचन्द्रबिम्बोपरिणतकदम्बप्रोतवृत्त क्रान्तिवृत्त में जहाँ लगता है वह बिन्दु) तद्गोलीय स्पष्टचन्द्र है। इस तरह भूगर्भगोल में भी स्पष्टचन्द्र स्थान समझना।

उपपत्ति के लिए परिभाषाएँ

वेधगोलीय चन्द्रस्थान=स्थान स्थानीय दृष्टवृत्त धरातल से कटित भूगर्भगोल का प्रदेश उस गोल का दृष्टवृत्त होता है। भूगर्भगोलीय दृष्टवृत्त और भूगर्भगोलीय क्रान्तिवृत्त के योग बिन्दु =ष, भूगर्भ से ष बिन्दुगत रेखा=प संज्ञक। दृष्टि-स्थान से स्थानगत रेखा=फ संज्ञक। प और फ रेखा समानान्तर हैं (रेखापरिणत एकादशाध्याय युक्ति से), भूगर्भ से तथा दृष्टिस्थान से रेवतीगत रेखाद्वय समानान्तर है अतः भूगर्भलग्न कोणमान और दृष्टिस्थानलग्न कोणमान समान हुआ अर्थात् भूगर्भगोल (भगोल) में रेवती से ष बिन्दुपर्यन्त चाप वेधगोलीय स्पष्टचन्द्र के बराबर हुआ, अर्थात्

भगोलीय रेवती से र बिन्दुपर्यन्त=वेधगोलीय रेवती से स्थान पर्यन्त; क्योंकि केन्द्रलग्न कोण का मान तत्संमुखचाप होता है। स्थानीयनतांश=ष बिन्दुपर्यन्त नतांश क्योंकि प, और फ रेखा समानान्तर हैं। वह नतांश वेधगोल में मापन

करने से विदित हुआ । तथा चन्द्रबिम्बीयनतांश और प-विन्दूत्पन्न नतांश चापों से उत्पन्न खस्वस्तिक लग्नकोण जितने वेधगोल में होते हैं उतने ही भूगर्भगोल में भी, क्योंकि दोनों गोलों में घरातल एक ही है । अतः प्रहों के दिगंशवश वह कोण का मान निकालना होगा तब भूगर्भगोल पृष्ठ पर जो त्रिभुज बना है उसमें 'त्रिज्या-गुणाद्वरणि कोटिगुणात्' इत्यादि के विलोम से परिणत चन्द्रबिम्ब केन्द्र प विन्दु-गतवृत्तीयाधार चापज्ञान हुआ । तथा वेधगोलीयशर, क्रान्तिवृत्तघरातलान्तर के ज्ञान से भूगर्भगोल में शरज्ञान (वेधगोलीय और भूगर्भगोलीय नाडीवृत्तघरातलान्तर और वेधगोलीय क्रान्तिज्ञान से भूगर्भगोलीय क्रान्तिज्ञान के लिए जो युक्ति है उसी तरह की युक्ति शरज्ञान के लिए है), इस लिए चापजात्य युक्ति से भूगर्भगोलीय स्पष्टचन्द्र और प विन्दु के अन्तर संस्कारसंज्ञक चाप का ज्ञान हो जायगा । अन्तर=संस्कारचाप ।

अतः वेधगोलीयस्प चन्द्र \pm संस्कारचाप=भूगर्भगोलीय स्प चन्द्र ।

अब संस्कार चाप की घन और ऋण की व्यवस्था दिखलाते हैं ।

परिभाषाएँ

वेधगोलीयक्रान्तिवृत्त = इष्टक्रान्तिवृत्त । भूगर्भगोलीयक्रान्तिवृत्त=वास्तव-क्रान्तिवृत्त । बिम्बीय कर्णगोलीय क्रान्तिवृत्त=वास्तवक्रान्तिवृत्त । 'प' रेखा बढ़कर वास्तव क्रान्तिवृत्त में जहाँ लगती है वहाँ प विन्दु है, चन्द्रबिम्ब केन्द्र से इष्ट क्रान्तिवृत्त घरातल का जो शरज्यालम्ब है उसका मूल विन्दु=क्ष, यह विन्दु बर्धित फ रेखा ही में होता है । फ-रेखा स्थानीय दृष्ट वृत्त घरातल में है । पूर्वकथित शरज्या बढ़कर या नहीं बढ़कर वास्तव क्रान्तिवृत्त घरातल के ऊपर लम्ब है । स्थानीय दृष्टवृत्तघरातलनिष्ठ 'क्ष' विन्दु से वास्तव क्रान्तिवृत्त घरातल के ऊपर लम्ब करते हैं, उसका मूल विन्दु स्थानीय दृष्टवृत्त घरातल और वास्तव क्रान्तिवृत्त घरातल से उत्पन्न कोण जिस दिशा में अल्प है उसी दिशा में पतित होगा ।

अब भूगर्भ से बिम्बीय कर्णव्यासार्ध से जो गोल होता है उस पर विचार करते हैं ।

प विन्दुजनित दृष्टवृत्त और वास्तवक्रान्तिवृत्त से उत्पन्न दृक्षेय चापभिमुख कोण अल्प है, क्ष विन्दु तो वास्तव क्रान्तिवृत्त घरातल और ऊर्ध्वाधर सूत्र के मध्य (बीच) में है क्योंकि फरेखा मध्य में है । इससे सिद्ध होता है कि दृक्षेय वृत्त से पूर्वकपाल में चन्द्र के रहने से रेखा से पश्चिम दिशा ही में लम्बमूल गिरेगा, क्योंकि स्थानीय दृष्टवृत्त घरातल और क्रान्तिवृत्त घरातल की योगरेखा प-रेखा है । भूगर्भ से लम्बमूलगतरेखा प विन्दु से पश्चिम दिशा ही में क्रान्तिवृत्त में लगेगी वही विन्दु भूगर्भाभिप्रायिक चन्द्र-स्थान है । त्रिज्यागोल में भी यही स्थिति है । पश्चिम कपाल में भी इसी तरह विचार करना । इससे सिद्ध होता है कि विभिन्न से चन्द्र के अल्प रहने से संस्कारचाप घन होता है अन्यथा ऋण होता है इति ॥

अब पूर्वोपपत्ति में वेधगोलीय नाड़ीवृत्त धरातल और भूगर्भगोलीय नाड़ीवृत्त धरातलान्तर ज्ञान से तथा वेधगोलीय क्रान्तिज्ञान से भूगर्भगोलीय क्रान्तिज्ञान के लिए जो युक्ति है उसी तरह की युक्ति वेधगोलीय शर और क्रान्तिवृत्तधरातलान्तर ज्ञान से भूगर्भगोलीय शरज्ञान के लिए होती है यह हमने जो लिखा है उसके लिए विचार करते हैं । दृष्टिस्थान से जो गोल बनाया जाता है उसको वेधगोल या दृश्यगोल कहते हैं । और भूगर्भ से जो गोल बनता है उसे स्थिरगोल या भगोल कहते हैं । भूगर्भ से और दृष्टिस्थान से भ्रूवतारागत रेखाद्वय अपने अपने गोल (भूगर्भगोल और वेधगोल) में जहाँ जहाँ लगता है वहाँ वहाँ दोनों गोलों में परिणत ध्रुव होता है । इन दोनों (परिणत ध्रुवबिन्दुओं से नवत्यंश जो वृत्त बनते हैं वे दोनों गोल में नाड़ीवृत्त होते हैं, भूगर्भ से और दृष्टिस्थान से ध्रुवगत रेखाद्वय और भूगर्भदृष्टिस्थान से जो त्रिभुज बनता है उस त्रिभुजरूपी धरातल से कटित गोलद्वय का प्रदेश गोलद्वय में याम्योत्तरवृत्त होता है, स्वनाड़ीवृत्त धरातल और याम्योत्तर वृत्त धरातल की योगरेखा स्वनिरक्षोर्ध्वाधिरसूत्र है, वर्धित भूकेन्द्रदृष्टिस्थानान्तरेखा ऊर्ध्वाधर सूत्र है । नाड़ीवृत्त धरातल के ऊपर ध्रुवसूत्र लम्ब है परन्तु दोनों गोलों के ध्रुवसूत्र समानान्तर हैं इसलिए दोनों गोलों के नाड़ीवृत्त धरातल समानान्तर हुए (रेखागणित की एकादशाध्याययुक्ति से), दृष्टिस्थान से भगोलीय नाड़ीवृत्त धरातल के ऊपर जो लम्ब होता है वही वेधगोलीय और भगोलीय नाड़ीवृत्त धरातलान्तर है, दोनों गोलों में अक्षांश समान होने से नाड़ीवृत्त धरातलान्तर ज्ञान करते हैं ।

भूगर्भ से दृष्टिस्थान पर्यन्त (केन्द्रान्तर) एकभुज । दृष्टिस्थान से भगोलीय नाड़ीवृत्तधरातल के ऊपर लम्ब (नाड़ीवृत्तधरातलान्तर) द्वितीय भुज, गर्भीय निरक्षोर्ध्वाधररेखाखण्ड तृतीय भुज, इन तीनों भुजों से उत्पन्न जात्यत्रिभुज में भूगर्भलम्ब कोण = अक्षांश, लम्बमूल बिन्दुलम्बकोण = ९०, अतः अनुपात करते हैं यदि त्रिज्या कोणज्या में केन्द्रान्तर पाते हैं तो अक्षज्या कोणज्या में क्या इस अनुपात से नाड़ीवृत्त धरातलान्तर प्रमाण आता है; $\frac{\text{अज्या} \times \text{केन्द्रान्तर}}{\text{त्रि}} = \text{नाड़ीवृत्तधरातलान्तर}$ । दृष्टिस्थान से स्वगोलस्थ रविगतरेखा और स्वनाड़ीवृत्त (वेधगोलीयनाड़ीवृत्त) धरातल के अन्तर वेधगोल में वेधगोलीय क्रान्तिज्या है । वेधगोलीय क्रान्तिज्या मापनद्वारा विदित है इसलिए $\frac{\text{वेधगोलीय क्रान्तिज्या} \times \text{दृष्टिकर्ण}}{\text{वेधगोल व्यास}} = \text{ग्रह से निरक्षोर्ध्वाधर सूत्र के ऊपर लम्बरेखा} = \text{लम्ब}$ । अतः लम्ब \pm नाड़ीवृत्त धरातलान्तर = लम्ब \pm अन्तर = ग्रहगोलीय क्रान्तिज्या । इसके ज्ञानसे $\frac{\text{ग्रहगोलीय क्रान्तिज्या} \times \text{त्रि}}{\text{अविकर्ण}} = \text{भगोलीय क्रान्तिज्या} = \text{भूगर्भगोलीय क्रान्तिज्या} = \text{स्थिरगोलीय क्रान्तिज्या}$, इस रीति से वेधगोलीय शरज्ञान से क्रान्तिवृत्त धरातलान्तरज्ञान से भूगर्भगोलीय शरज्ञान होता है ।

यहां(B) क्षेत्र देखिये ।

र = रवि । ख = भगोलीय खस्वस्तिक । खं = वेधगोलीय खस्वस्तिक,

क्रान्तिज्या ।

रविमन्दोच्चोपपत्ति

भूकेन्द्र से रविमन्दगोल केन्द्रगतरेखा रविमन्दप्रतिवृत्त में जहाँ लगती है वही रवि के मन्दोच्च है । (भूकेन्द्र से मन्दप्रतिवृत्तीय अन्य बिन्दुओं से वह बिन्दु अधिक उच्च में है इसलिए उसका उच्चनाम अनुगतार्थ है, रविकर्ण में यदि त्रिज्या पाते हैं तो रवि बिम्ब व्यासार्ध में क्या—इस अनुपात से फल आता है उसके चाप को द्विगुणित करने से रवि के बिम्बकला प्रमाण होता है । प्राचीनार्च्य लोग अनुपात से जो फल आता है उसीको द्विगुणित कर चाप करते हैं उसीको बिम्बकला-मान कहते हैं यह ठीक नहीं है, बिम्बकलानयन प्रकार के देखने से उच्चस्थान में रविकर्ण के परमत्व के कारण रविविम्बकलाप्रमाण परमाल्प सिद्ध होता है । 'लम्बनावनतिदर्शनार्थमियं भूरन्यथा केवलं बिन्दुरेव भूः' इस भास्करोक्ति से यहां भूगर्भ और भूपृष्ठ में अभेद मानकर भूकेन्द्रलग्न कोण (रविविम्बकला) को मापन कर जान लिया जाय तब रवि बिम्बकला के परमाल्पत्व वेधागत स्पष्ट रवि ही रवि-मन्दोच्च होंगे । द्वितीय पर्यय में भी इस तरह रविमन्दोच्च ज्ञान कर दोनों रवि-मन्दोच्चों के अन्तर करने से वेधदिनान्तरजनित रविमन्दोच्च गति होगी । तब अनुपात करते हैं यदि इन वेधदिनान्तर में यह रविमन्दोच्च गति पाते हैं तो एक दिन में क्या इस अनुपात से एकदिनसम्बन्धिनी रविमन्दोच्च गति आई । फिर अनुपात करते हैं यदि एक दिन में यह रविमन्दोच्च गति पाते हैं तो कल्पकुदिन में क्या इससे कल्परविमन्दोच्च भगण आया ।

अथवा विदित रविमन्दोच्च ७८° से कुट्टकयुक्ति से उसका (रविमन्दोच्च) आनयन करते हैं ।

कल्पना करते हैं कल्परविमन्दोच्चभगणमान = य

तब १८५३ शकान्त में कल्पादि से सौर वर्ष = १९७२९४१०३२ (नव-नगशशिमुनिकृतनव इत्यादि ब्राह्मस्फुटसिद्धान्तोक्ति से या गोप्त्रीन्द्रद्विकृताङ्कदक्ष-नगगोचन्द्रा इत्यादि भास्करोक्ति से) तब अनुपात करते हैं यदि कल्प सौर वर्ष में कल्परविमन्दोच्च भगण पाते हैं तो कल्पादि से शकान्त तक पूर्वानीत सौर वर्ष में क्या—इससे शेषतहित रविमन्दोच्चभगण इष्टवर्षान्त में आया ।

$$\frac{१९७२९४१०३२ \times य}{४३२०००००००} = ल + \frac{७०}{४३२०००००००} \therefore १९७२९४१०३२ \times य =$$

४३२००००००० × ल + ७० समशोधन करने से १९७२९४१०३२ × य = ४३२०००००००

× ल = शे इसको चक्रांश (३६०) से गुणाकर कल्प वर्ष से भाग देना तब फल
रविमन्दोच्च प्रमाण = ७८ ∴ $(१६७२६४१०३२ \times य - ४३२०००००० \times ल) \times ३६०$
४३२००००००

= ७८° छेदगम से

$(१६७२६४१०३२ \times य - ४३२०००००० \times ल) \times ३६० = ४३२०००००० \times ७८ -$

दोनों पक्षों को ३६० इस से भाग देने से

$१६७२६४१०३२ \times य - ४३२०००००० \times ल = \frac{४३२०००००० \times ७८}{३६०} = १२००००० -$

०० × ७८ = ६३६०००००० दोनों पक्षों में समान जोड़ने से $१६७२६४१०३२ \times य =$

$४३२०००००० \times ल + ६३६०००००० ∴ \frac{१६७२६४१०३२ \times य - ६३६००००००}{४३२००००००} = ल।$

आठ से भाग देने से $\frac{२४६६१८६२६ \times य - ११७००००००}{५४००००००} = ल$, यहां ५५६७०१ इन

से अपवर्त्तन देने से $\frac{४४३५ - २१०}{६७०} = ल$ (स्वल्पान्तर से) ऋणात्मक रूपक्षेप में लब्धि

और गुण लाकर 'अभीप्सितक्षेपविशुद्धिनिघ्नी' इत्यादि से लब्धि = २१६, गुणक
= ४८० 'ते भाज्यतद्भाजकवर्णमाने' इस भास्करोक्ति से गुणक ही भाज्यवर्ण (य)
का मान होता है इसलिए य = ४८० = कल्परविमन्दोच्च भगण।

चन्द्रमन्दोच्चोपपत्ति

दो तरह के मन्द और शीघ्र भेद से मन्दोच्च और शीघ्रोच्च होता है।
'शीघ्राख्यतुङ्गस्य तयोरभावात्' इत्यादि भास्करोक्ति से रवि और चन्द्र का केवल
मन्दोच्च ही होता है। चन्द्रबिम्ब कला की परमाल्पता चन्द्रमन्दोच्च स्थान में होती है
वहां उस समय में जितने वेधगत स्पष्ट चन्द्र होते हैं उतने ही चन्द्रमन्दोच्च होते
हैं। परमाल्पचन्द्रबिम्बकलाप्रमाण को मापन कर समझ लेना चाहिए इसके
लिए भूगर्भ और भूपृष्ठ को अभेद मानना पड़ेगा, द्वितीय पर्यय में भी पूर्वोक्त
युक्ति से चन्द्रमन्दोच्च जानकर दोनों चन्द्रमन्दोच्च के अन्तर करने से वेधकालान्तर दिन-
सम्बन्धी चन्द्रगति होती है तब अनुपात करते हैं यदि वेधकालान्तर में चन्द्रगति पाते
हैं तो एक दिन में इससे एकदिनसम्बन्धिनी चन्द्रमन्दोच्च गति आई, इससे
पूर्ववत् कल्प चन्द्रभगण ले आना। बिम्बीय कर्णसम्बन्ध से भी चन्द्रमन्दोच्च
भगणोपपत्ति हो सकती है। यथा

प्रत्येक दिन वेध से चन्द्रबिम्बीय कर्ण साधन करना, जब चन्द्र शराभाव होगा
उस दिन में चन्द्रबिम्बीय कर्ण के परमत्व में वेधगत स्पष्ट चन्द्र ही मन्दोच्च होंगे। द्वितीय
पर्यय में भी इसी तरह चन्द्रमन्दोच्चों के अन्तर पर से पूर्ववत् कल्पचन्द्र मन्दोच्च भगण
आ जाएंगे।

चन्द्रपातभगणोपपत्ति

दृष्टिस्थानाभिप्रायिक गोल का निर्माण करना ही वेधगोल है। दृष्टिस्थान (वेध-

गोल केन्द्र) से चन्द्र को वेध करने से वेधगोल में जहाँ उपलब्ध होते हैं उनके ऊपर वेध-गोलीय कदम्ब प्रोतवृत्त करने से वह कदम्ब प्रोतवृत्त वेधगोलीय क्रान्तिवृत्त में जहाँ लगता है वहाँ से चन्द्रविम्बकेन्द्र तक कदम्ब प्रोतवृत्त में चन्द्र का शरांश है, तब

वेधगोलीय शरज्या \times त्रि
वेधगोलव्या $\frac{1}{2}$ —चन्द्रगोलीयशरज्या । इसमें क्रान्तिवृत्त घरातलान्तर संस्कार करने

से जो होता है उसके बश से भगोलीय शरज्ञान होगा ही, इस तरह प्रत्येक दिन वेध से भगोलीय शरज्या का ज्ञान करना ॥१३॥

इदानीं ग्रहयुगस्य परिभाषां करोति

कालर्क्षदेशयोगाद् भूयो ग्रहमन्दशीघ्रपातानाम् ।

कल्पेन यतो योगस्ततः स्फुटं ग्रहयुगं कल्पः ॥१४॥

वा. भा.—कालयोगः चैत्रसितादेरुदयाद् भानोः । ऋक्षयोगः पौष्णाश्विनांतरस्थैः सह ग्रहैः । देशयोगो लङ्कायामिति । तेनायमर्थः, कालर्क्षदेशयोगाद् भूय एतावत्या सामग्र्या पुनरपि ग्रहशीघ्रमन्दपातानां यतो यस्मात्कल्पे योगो भवति तस्मात् कल्प एव ग्रहयुगं स्फुटम् ॥

वि. भा.—ग्रहमन्दशीघ्रपातानां (ग्रहाणां मन्दोच्चानां शीघ्रोच्चानां पातानां च) कालर्क्षदेशयोगात् (कालयोगश्चैत्रसितादेरुदयाद्भानोः) ऋक्ष (नक्षत्र) योगः पूर्वकथितैः पौष्णाश्विन्यन्तस्थैः सह ग्रहैः देशयोगः (लङ्कायाम्) एतस्मात्कालर्क्षदेश-योगाद्, भूयः (बारं बारं) यतः (यस्मात्कारणात्) कल्पेन (कल्पवर्षप्रमाणेन) योगो भवेन्नहि तत्पूर्वं पश्चाद्वा ततः (तस्मात्कारणात्) कल्पो ग्रहयुगमिति स्फुटमर्थाद्यदैकदा सृष्ट्यारम्भे कल्पादौ ग्रहमन्दशीघ्रपातानां कालदेशयोगो भवति ततोऽनन्तरं पुनः कल्पान्ते (द्वितीयसृष्ट्यारम्भे) तादृशयोगः कल्पवर्षैर्भवत्यतः कल्प एव ग्रहयुगमिति ॥१४॥

अब ग्रहयुग की परिभाषा करते हैं ।

हि. भा.—ग्रहों, मन्दोच्चों, शीघ्रोच्चों और पातों के कालसम्बन्ध से योग हो (पहले सृष्ट्यारम्भ में जो कहा गया है चैत्रसितादेरुदयाद्भानोः) ऋक्ष (नक्षत्र) योग (पूर्वकथित भवक्रवचलनसूत्रक श्लोक में पौष्णाश्विन्यन्तस्थैः सह ग्रहैः) देशयोग (पूर्वकथित काल प्रवृत्ति-सूचक श्लोक में) 'लङ्कायाम्' इस तरह की स्थिति जब (कल्पादि में) हो उसके बाद फिर उन सब ग्रहमन्दशीघ्रपातों के वह योग कल्पवर्ष में होता है इसलिए कल्प ही स्फुट ग्रह युग होता है । अर्थात् ग्रहादि के कालयोग, ऋक्षयोग और देशयोग, एकबार जब (कल्पारम्भ में) होता है फिर उन सब के उस तरह के योग कल्पवर्ष में (कल्पान्त में) होता है उससे पहले या पीछे नहीं होता है इसलिए कल्पादि से कल्पान्त पर्यन्त एक कल्पवर्ष ही ग्रहयुग होता है । इति ॥१४॥

अब भ्रम को और कुदिनों को कहते हैं ।

हि. भा.—कल्प में १५८२२३६४५०००० इतने भ्रम होते हैं, भ्रम में रविभगण को घटाने से रवि के सावन दिन होते हैं वह कुदिनसंज्ञक हैं अर्थात् कल्प या युग में जो सूर्यसावन दिन होते हैं उन्हीं को कल्प या युग में कुदिन कहते हैं ॥२२॥

उपपत्ति

एक दिन में उदय काल में किसी नक्षत्र के साथ रवि उदित हुए, दूसरे दिन में नक्षत्र की गति नहीं रहने के कारण पहले नक्षत्र का उदय होता है उसके बाद रविगति-कलोत्पन्नासु करके रवि का उदय होता है इसलिए एक नाक्षत्र दिन में रविगतिकलोत्पन्नासु जोड़ने में एक सावन दिनान्तःपाती नाक्षत्र काल होगा । एवं दूसरे दिन में दो नाक्षत्र दिन में दो दिनों के रविगतियोगकालोत्पन्नासु से दो सावन दिनान्तःपाति नाक्षत्र काल होगा । इसी तरह तीसरे, चौथे आदि दिनों में भी विचार करना । इससे यह देखने में आता है कि जिस इष्टदिन में नाक्षत्र काल अपेक्षित हो उस दिन के संख्यातुल्य नाक्षत्र दिन में एक वर्ष सम्बन्धित रविगतियोगा (क्रान्तिवृत्त) सु (एक नाक्षत्र दिन) जोड़ने से एक वर्षान्तःपाति नाक्षत्र दिन अर्थात् एक वर्षान्तःपाति भ्रम होता है । इसलिए वर्षान्तः-

पतिभभ्रम=वर्षान्तःपाति रविसावनसं + १ नाक्षत्र दिन तब अनुपात यदि एक वर्ष में यह वर्षान्तःपाति भभ्रम पाते हैं तो कल्पवर्ष में क्या, इससे कल्प में भभ्रम=(वर्षान्तःपाति रसावन सं + १) × कवर्ष=वर्षान्तःपाति रसावन सं × कवर्ष=कल्परविसावनदि + कवर्ष=कल्पकुदिन + क रविभगण=पठिताङ्क तथा कल्पभभ्रम—कल्परविभगण=ककुदिन (भास्कराचार्य भी खषेपुवेदषड्गुणा कृतीभभूतभूमयः । शताहता भपश्चिमभ्रमा भवन्ति काह्नि' इससे वही कहते हैं इति ॥ २२ ॥

अथैकसावनदिने $\left\{ \begin{array}{l} \text{चान्द्रमध्यगतिः} = ७६०' १३'' \\ \text{रविमध्यग} = ५६' १८'' \end{array} \right\}$ अनयोरन्तरम् = $७३१' १२''$
 = $१२^{\circ} ११' १२''$

अथ यतः चंग—रग = $१२' = १$ तिथिस्तस्मात्सावनदिनपूर्तिकालात् पूर्वमेव चान्द्रदिनपूर्तिः सिद्धाऽतः चान्द्रदि < सावनदि < सौरदिन यतः सौरदि = $६०'$, यदा रविगतिः षष्टिकला भवेत्तदा सौरदिनपूर्तिः, सावन-दिन-पूर्तिरस्ति $५६' १८''$ एतत्तुल्यरविगतावेवातो दिनसंख्यया सौरदिसं < चान्द्र दिवसम्

ततः कचान्द्रमास—कसौरमास = कल्पाधिमास, कचांदिन—कसावनदि = कक्षयदिन = कल्पावमदिन एतेन 'शशिमासाः सूर्यमासोना' इत्यारभ्य 'शशिसावन-दिवसान्तरमवमानोत्यन्तमुपपद्यते । भास्कराचार्येणापि 'सौरान्मासादैन्दवः स्याल्लघीयान् यस्मात्तस्मात्संख्यया तेषुधिकाः स्युरित्यादिना तदेव कथ्यत इति ॥२४॥

अब सौरमास चान्द्रमास अधिमास और अवमदिन को कहते हैं

हि.भा.—कल्प पठित रविभगण ४३२००००००० कल्पसौरवर्ष होते हैं अर्थात् कल्प में जितने रविभगण हैं उतने ही कल्पसौरवर्ष होते हैं, कल्पसौरवर्ष को बारह से गुणने से कल्पसौरमास होते हैं, कल्पचन्द्रभगण और कल्परविभगण का अन्तर कल्प चान्द्रमास होते हैं। कल्पचान्द्रमास में कल्प सौरमास को घटाने से कल्पाधिमास होता है। कल्पचान्द्रमास को तीस से गुणने से कल्पचान्द्रदिन होते हैं, कल्पचान्द्रदिन और कल्पकुदिन का अन्तर कल्पावमदिन होते हैं। एक तिथि एकचान्द्रदिन है ॥२३-२४॥

इन सब की उपपत्ति

सृष्ट्यादि काल में नाड़ीवृत्त और क्रान्तिवृत्त के सम्पात (स्थिरमेघादि) में रवि थे। उसके बाद रवि भ्रमण करते हुए फिर जब उसी बिन्दु में आते हैं तब उनकी एक भगण (द्वादशराशिभोग) पूर्ति होती है लेकिन इतने समय में वह सम्पात भी कुछ पूर्व स्थान से चलेगा, इसलिए पूर्वकथित रवि के एकभगणभोग कालतुल्य सौरवर्ष में सम्पात चलन (अयनगति) जोड़ने से वास्तव सायन सौरवर्ष होगा। परन्तु यहां आचार्य निरयण सौरवर्ष ही लेते हैं, कल्पसौरवर्ष भी निरयण ही कहते हैं।

कल्पसौरवर्ष $\times १२$ = कल्पसौरमास 'इससे (रविभगणरव्यब्दाः) यह आचार्यकथन निरयणसौरवर्षपरक समझना चाहिए, भास्कराचार्य भी 'रवेश्चक्रभोगोऽर्कवर्ष-प्रदिष्टम्' इससे जो एक रविभगण भोगकाल को एक सौरवर्ष कहते हैं वह भी निरयण सौरवर्ष ही सिद्ध होता है, सब आचार्य यहां अयनगति को गृह्य मानते हैं जो ठीक नहीं है ॥

चान्द्रमास की उपपत्ति

अमान्तकाल में रवि और चन्द्र एक ही स्थान में रहते हैं, उसी का नाम द्रवन्ति

(अमान्त) है उसके बाद रवि और चन्द्र अपनी-अपनी गति से चलने लगे, चन्द्र गति की अधिकता के कारण जिस स्थान (अमान्त बिन्दु) से चले थे वहाँ जाकर फिर रवि के साथ योग करते हैं तब एक चान्द्रमास (प्रथमामान्त से द्वितीयामान्त तक) भी पूरा हो जाता है यहाँ पर चन्द्रगति = १ चन्द्रभरण + रविगति हुई क्योंकि जिस स्थान से (प्रथमामान्तबिन्दु) चले थे वहाँ फिर जाने से चन्द्र की एक भरण पूर्ति होती है इसलिए चन्द्रगति—रविगति=चन्द्रभरण, तब अनुपात करते हैं यदि एक चन्द्रभरणतुल्य रविचन्द्र गत्यन्तर में एक चान्द्रमास पाते हैं तो कल्पीय रविचन्द्रगत्यन्तर (कल्पीय रविचन्द्रभरणान्तर) में क्या इस अनुपात से कल्पचन्द्र भरण और कल्परविभरण के अन्तर तुल्य ही कल्पचान्द्रमास सिद्ध हुआ इससे 'भरणान्तरं रवीन्द्रोः शशिमासाः' यह उपपन्न हुआ ॥

अधिमास की उपपत्ति

कल्पचान्द्रमास में कल्प सौरमास को घटाने से कल्पाधिमास क्यों होता है इसके लिए विचार करते हैं ।

एक सावन दिन में चन्द्र मध्यमगति = ७६०' १३५'' दोनों के अन्तर = ७३१' १२७'' =
रविमध्यमगति = ५६' १८''

१२१' ११' १२७'' = चमग—रमग तथा चमग—रमग = १२' = १ तिथि इसलिए सावन दिन पूर्ति (पूरा) काल से पहले ही चान्द्रदिन पूर्ति सिद्ध हुई ।

अतः चान्द्रदिन < सावनदि < सौरदिन, क्योंकि जब रवि की मध्यमगति साठ कला के बराबर होती है तब सौर दिन पूर्ति होती है और ५६' १८'' इतनी रवि मध्यमगति में सावन दिन पूर्ति होती है इसलिए दिन संख्या से सौ दिसं < चांदिसं अतः कल्पचान्द्रमास—कल्पसौर मास = कल्पाधिमास, तथा कल्पचांदि—कसावनदि = कक्षयदि = कल्पावमदि इससे शशिमासा रविमासोना—यहाँ से 'शशिसावनदिवशान्तरमवमानि' यहाँ तक उपपन्न हुआ ॥ २४ ॥

अब सावन दिन नाक्षत्र दिन मानव वर्ष पितृदिन और दिव्य दिनों को कहते हैं

हि. भा.—रवि के उदय से द्वितीय उदय पर्यन्त रविसावन दिन है, नक्षत्रोदय से
नक्षत्रोदय तक नाक्षत्रसावन दिन होता है; एवं किसी ग्रह के उदय से उदय तक उस ग्रह का
दिन सावन होता है । मानव वर्ष सौर वर्ष के बराबर होता है । पितरों का दिन चान्द्रमास
के बराबर होता है, रविभगण के बराबर दिव्य (देवताओं के) दिन होते हैं ॥ २५ ॥

इन सब की उपपत्तियाँ

सावनदिन, मानववर्ष ये परिभाषा रूप में कहे जाते हैं, अब पितरों का दिन (अहोरात्र)
एक चान्द्रमास के बराबर क्यों होता है इसके लिए विचार करते हैं । चन्द्र के ऊर्ध्वपृष्ठ पर

पितर लोग बसते हैं ऐसा पुराणादियों में कहा गया है, इसी के अवलम्बन से विचार करते हैं। चन्द्र के ऊर्ध्वपृष्ठ (ऊर्ध्वभाग) से कितना भाग ग्रहण करना चाहिए। दृष्टिस्थान (भूकेन्द्र) से चन्द्रविम्ब की अनेक स्पर्शरेखा करने से प्रत्येक स्पर्शबिन्दुजनित चन्द्रविम्बप्रदेश गृह्यत कार होता है; चन्द्रविम्ब में इसको घटाने से जो शेष रहता है वही चन्द्र का ऊर्ध्व भाग है। वहां पितर लोग वास करते हैं, यह पुगणादि वचनों से विदित होता है। भूकेन्द्र से चन्द्रकेन्द्रगत रेखा पितरों के त्रिज्यागोलीय याम्योत्तरवृत्त में जहां लगती है वही पितरों के त्रिज्यागोल में परिणत चन्द्र है और पितरों का ऊर्ध्व खस्वस्तिक भी है। वहां जब रवि आयेंगे तो रवि और चन्द्र के एक स्थान में रहने के कारण अमान्तकाल होगा और वहीं परिणत चन्द्र पितरों का ऊर्ध्व खस्वस्तिक है और वहीं रवि भी है इसलिए ऊर्ध्व खस्वस्तिक में रवि के जाने से दो प्रहर (दिनार्ध वा मध्याह्न) होता है अतः सिद्ध हुआ कि अमान्तकाल में पितरों का दिनार्धकाल होता है। फिर दूसरा अमान्तकाल जब होगा तो पितरों के वहां दूसरा दिनार्धकाल होगा, अतः प्रथम अमान्त से द्वितीय अमान्त तक (एक चान्द्रमास) प्रथम दिनार्ध से द्वितीय दिनार्ध तक काल के बराबर हुआ। परन्तु प्रथम दिनार्ध से द्वितीय दिनार्ध तक काल प्रथम सूर्योदय से द्वितीय सूर्योदय तक काल (अहोरात्र) के बराबर होता है इसलिए पितरों का अहोरात्र एक चान्द्र मास के बराबर सिद्ध हुआ। परन्तु यहां अमान्तकाल में पितरों का मध्याह्नकाल स्वीकार कर विचार किया गया है, यह ठीक नहीं है। सिद्धान्त गिरोमणि में भास्कराचार्य ने भी 'दर्शे यतोऽस्माद् द्युलं तदंशम्' इससे अमान्तकाल ही में पितरों का दिनार्धकाल स्वीकार किया है, पितरों के याम्योत्तरवृत्त में अर्थाच्चन्द्रोपरिगत अवप्रोत्तवृत्त में जब रवि आते हैं तभी उनका दिनार्धकाल होता है, चन्द्रोपरिगतकदम्बप्रोत्तवृत्त ही यदि पितरों का याम्योत्तरवृत्त हो तभी अमान्तकाल और पितृमध्याह्नकाल में अभेदत्व होगा। लेकिन ऐसी स्थिति चन्द्रशराभाव स्थान में और चन्द्र की सत्ता में भी चन्द्र के मिथुनांत में रहने से होती है। यथा भूकेन्द्र से चन्द्रवेन्द्रगत रेखा पितृगोल में जहां लगती है वहीं यदि रविकेन्द्र होगा तभी उसी अमान्त बिन्दु में चन्द्र के शराभाव के कारण मध्याह्नकाल और अमान्तकाल में अभेदत्व होगा। और मिथुनांत में विमण्डल में चन्द्र के रहने से उसी अयन प्रोत्तवृत्त और क्रान्तिवृत्त के योगबिन्दु में जब रवि होंगे तभी अमान्तकाल और पितृमध्याह्नकाल में अभेदत्व होता है। इन दोनों स्थानों से भिन्न स्थल में अमान्तबिन्दु से अर्थात् चन्द्रोपरिगतकदम्बप्रोत्तवृत्त और क्रान्तिवृत्त के योगबिन्दुस्य रविबिन्दु से पितरों के याम्योत्तरवृत्त पूर्व या पश्चिम में होता है। वहां अमान्तकाल से जितने काल में पितृयाम्योत्तरवृत्त में रवि होता है वह काल अयनद्वकर्मसितुल्य है, उस काल (अयनद्वकर्मसु) करके यदि अमान्तकाल का संस्कार करते हैं तब पितृयाम्योत्तरवृत्त में रवि होता है वही वास्तव पितृमध्याह्नकाल है।

यहां (क) क्षेत्र देखिए। रन = अयनद्वकर्मकलासु। अतः अमान्तकाल \pm अयनद्वकर्मसु = वास्तव पितृदिनार्ध, इसी के वश से रात्र्यर्ध भी समझना चाहिए।

पितरों के ऊर्ध्व खस्वस्तिक में (परिणत चन्द्रबिन्दु में) रवि के रहने से अमान्तकाल में उनका दिनार्ध होता है। परिणत चन्द्र से छह राशि अन्तर पर अर्धः खस्वस्तिक में रवि

के रहने से पूरणि काल में पितरों का रात्र्यर्ध सिद्ध होता है। अब पितरों का उदयकाल और अस्तकाल कहां कहां होता है इसके लिए विचार करते हैं। भूकेन्द्र से चन्द्रकेन्द्रगत रेखा चन्द्रपृष्ठ में जहां लगती है उस बिन्दु में परिणत चन्द्र है और वही पितरों का ऊर्ध्व खस्वस्तिक भी है। पितृवस्वस्तिक से नवत्यंश व्यासार्ध से जो वृत्त होता है वह पितरों का क्षितिजवृत्त है, उसमें रवि के रहने पर परिणत चन्द्र और उस रवि में गये हुए वृत्त करते हैं उसका नाम सितवृत्त है। परिणत चन्द्रोपरिगत कदम्बप्रोतवृत्त करने से सितवृत्त कदम्बप्रोतवृत्त और क्रान्तिवृत्त के चापों से एक चापीय जात त्रिभुज बनता है, जिस में सितवृत्तीयचाप (क्षितिजवृत्तीय रविचन्द्रान्तरांश) कर्ण है, क्रान्तिवृत्तीयचाप (स्थानीय रवि चन्द्रान्तरांश) कोटि है, कदम्बप्रोतवृत्तीय चाप शर भुज है, इस चापीयजात्य त्रिभुज में सितवृत्तीय रवि-चन्द्रान्तरांश कर्णचाप = १० इमलिए गोलीयरेखागणित की युक्ति से क्रान्तिवृत्तीय रवि-चन्द्रान्तरांश कोटिचाप भी नवत्यंश के बराबर होगा, अतः पितरों के उदय और अस्त समय में सर्वदा रवि और चन्द्र का अन्तर नवत्यंश के बराबर होगा, क्योंकि परिणत चन्द्रोपरिगत कदम्बप्रोतवृत्त और क्रान्तिवृत्त का सम्पात बिन्दु चन्द्रस्थान है। इसलिए कृष्ण पक्ष के साढ़े सप्तमी में पितरों के उदय और शुक्ल पक्ष के साढ़े सप्तमी में अस्त समझना चाहिए। सिद्धान्तशिरोमणि में भास्कराचार्य कृष्णे रविः पक्षदलेऽभ्युदेति शुक्लेऽस्तमेत्यर्थत एव सिद्धम्' इससे यही बात कहते हैं, परन्तु भास्करकथित पितरों के उदयकाल और अस्तकाल का खण्डन म० म० पण्डित सुधाकर द्विवेदी ने किया है। जैसे—

भूकेन्द्र से चन्द्रकेन्द्रगत रेखा चन्द्रपृष्ठ में जहां लगती है उस बिन्दु से चन्द्रगर्भक्षितिज धरातल के समानान्तर करने से एक त्रिभुज बनता है, भूकेन्द्र से चन्द्रपृष्ठपर्यन्त चन्द्र-व्यासार्धयुत चन्द्रकर्ण कोटि प्रथमभुज। उदय और अस्तसमय में रविकेन्द्र सर्वदा पृष्ठ क्षितिज ही में रहते हैं इसलिए वहां के रविकर्ण कर्ण द्वितीयभुज, पृष्ठक्षितिज धरातल में तृतीयभुज, इन कोटि-कर्ण भुजों से उत्पन्न जात्यत्रिभुज में अनुपात करते हैं यदि रविकर्ण में त्रिज्या पाते हैं तो चन्द्रव्यासार्धयुत चन्द्रकर्ण में क्या आजायगी रविकेन्द्रलग्न कोणज्या = $\frac{\text{त्रि} \times (\text{चन्द्रकर्ण} + \text{चन्द्रव्यास} \frac{1}{2})}{\text{रविक}} \times$ इसके चाप = चा, नवत्यंश में घटाने से भूकेन्द्र-लग्न कोणप्रमाण अर्थात् सितवृत्तीय रवि चन्द्रान्तरांश = १०—चा, हुआ तब 'भक्ता-व्यर्कविधोर्लवा यमकुभिः' इत्यादि से पितरों के उदयकालिक गत तिथिप्रमाण = $\frac{१० - १}{१२} = \frac{९}{१२}$ इसको देखने से स्पष्ट है कि कृष्ण पक्ष की साढ़े सप्तमी में पितरों का उदयकाल नहीं होता है किन्तु साढ़े सप्तमी में $\frac{९}{१२}$ इतना घटाने से जो होता है उसमें उदयकाल सिद्ध हुआ, इसी तरह शुक्ल पक्ष की साढ़े सप्तमी में उनका अस्तकाल भी नहीं होता है अतः भास्करोक्त 'कृष्णे रविः पक्षदलेऽभ्युदेति' इत्यादि ठीक नहीं है; परन्तु म० म० पण्डित सुधाकर द्विवेदीकृत खण्डन में भी त्रुटि है; उपरि-लिखित खण्डनोपपत्ति में सितवृत्तीय रविचन्द्रान्तर पर से 'भक्ताव्यर्कविधोर्लवाः' इत्यादि से जो तिथिप्रमाण लाया गया है सो ठीक नहीं है। क्रान्तिवृत्तीय रविचन्द्रान्तर से तिथिगणन करना उचित है, इसलिए उक्त खण्डन भी दोषयुक्त है। अतः अब इसका वास्तवगणन प्रकार

दिखलाया जाता है। सितवृत्तीय रविचन्द्रान्तर कर्ण, क्रान्तिवृत्तीय रविचन्द्रान्तर कोटि, चन्द्र-शरभुज इस त्रिभुज में पूर्वोक्त नियम से सितवृत्तीय रविचन्द्रान्तरांश विदित है, और चन्द्रशर भी विदित है तब भुजकोटिज्या और कोटिकोटिज्या के घात त्रिज्या और कर्णकोटिज्या के घात के बराबर होता है इस नियम से सितवृत्तीयान्तर कोटिज्या \times त्रि = क्रान्तिवृत्तीयान्तर कोज्या \times शरकोज्या। दोनों पक्षों को (शरकोज्या) इस से भाग देने से—

$$\frac{\text{सितवृत्तीयान्तर कोज्या} \times \text{त्रि}}{\text{शरकोज्या}} = \text{क्रान्तिवृत्तीयान्तर कोज्या, इसके चाप को नवत्यश में}$$

घटाने से क्रान्तिवृत्तीय रविचन्द्रान्तरांश होंगे, इसके वश से पितरों की उदयकालिक तिथि और अस्तकालिक तिथि साधन करना वह वास्तविक तिथि होगी। इति।

अब दिव्य दिन रविभगण के बराबर होता है इसकी उपपत्ति दिखलाते हैं

देवों का ऊर्ध्व खस्वस्तिक उत्तर ध्रुव है, राक्षसों का ऊर्ध्व खस्वस्तिक दक्षिण ध्रुव है। खस्वस्तिक (ध्रुव) से नवत्यंश चाप व्यासार्ध से जो वृत्त (नाड़ीवृत्त) होता है वही उनका क्षितिज वृत्त है। नाड़ीवृत्त से उत्तर (मेषादि से कन्यान्त तक) जब रवि रहते हैं तब देवों का छः महीने का दिन होता है और राक्षसों की छः महीने की रात्रि होती है तथा नाड़ीवृत्त से दक्षिण (तुलादि से मीनान्त तक) रवि के रहने से देवों के छः महीने की रात्रि होती है और राक्षसों के छः महीने के दिन होते हैं। (क्षितिज से ऊपर रवि के रहने से दिन और उससे नीचे रहने से रात्रि होती है इस नियम से) इसलिए मेषादि से रवि के बारह राशि भोगकाल (एक रविभगण भोग) याने एक सौरवर्ष देव और राक्षस का अहोरात्र (दिन) सिद्ध हुआ। लेकिन रवि के एक भगण भोगकाल में सम्पात का भी कुछ चलन होगा उसी को अयन गति कहते हैं; इसलिए रवि के एकभगण भोगकाल में देव और राक्षसों के अहोरात्रान्त काशिक अयनगत्युत्पन्न काल का संस्कार करने से उन दोनों का वास्तव अहोरात्रमान होता है, यहाँ आचार्य ने अयनगति का ग्रहण नहीं किया है इसलिए उतनी त्रुटि है। भास्कराचार्य भी 'रवेश्चक्रभोगोऽर्कवर्षं प्रदिष्टम्' इत्यादि से वही बात कहते हैं इनमें भी वही त्रुटि है। यहाँ आचार्य 'दिव्यानि दिनानि 'रविभगणाः' इससे देव-सम्बन्धी दिन के विषय में कहते हैं, राक्षसों की चर्चा नहीं की है, देव और राक्षस का विलोम (उल्टा) करके रात्रि और दिन होते हैं लेकिन दिन और रात्रि दोनों की बराबर होती है। इसलिए देव अहोरात्र (दिन) के साथ ही राक्षस अहोरात्र भी दिखला दिये हैं। यदि दिव्य दिन से (राक्षस सम्बन्धी दिन भी) कहा जाय तब तो कोई बात कहने की जरूरत ही नहीं होगी। इति ॥ २५ ॥

इदानीं तत्सर्वस्यैव कोत्पत्तेरारभ्य गतकालस्य शककालस्य ग्रहगणितेऽ-
 हर्गणादयः प्राप्ता इत्येतदाशङ्क्य सयुक्तिकं परिहारमाह

कल्पपरार्धे मनवः षट्कस्य गताश्चतुर्गुणत्रिघनाः।

त्रीणि कृतादीनि कलेर्गोऽगैकगुणाः ३१७६ शकान्तेऽब्दाः ॥ २६ ॥

$$= १८४०३२०००० + १२०६६००० + ११६६४०००० + ३८८८०००० + ३१६$$

$$= १६७२६४७१७६ = \text{आचार्यपठिताङ्काः}$$

एतत्कथनस्येदं तात्पर्यं ग्रहादिचारसाधनं शकादेवाऽर्थाभटवटेश्वराचार्यो विहाय सर्वे प्राचीना नवीनाश्चात्रत्याः (भारतीयः) आचार्याः कृतवन्तः । कलियुगादित ३१७६ एतन्मितवर्षान्ते शकाब्दारम्भ इति गणकसमाजे जनश्रुता प्रसिद्धिरस्ति, तेन कलादितः शकान्तं यावत्कियन्ति सौरवर्षाणि गतान्येतत्प्रयोजन-मत्यावश्यकमतः पूर्वोक्तानां 'कल्पपार्ष्वमेव' इत्यादीनां योगकरणेन पूर्णोक्ता अङ्का जायन्त एतद्वशेनैवाङ्गणादीनां साधनं भवत्यत एतत्पाठकरणमतीवावश्यक-त्वादाचार्येण तेऽङ्काः पठिता इति । भास्कराचार्येणापि 'याताः षड् मनवो युगानि' भूमितानीत्यादिनैतदनुक्रमेण कथ्यते ॥ २६-२७ ॥

अब कल्पगत कहते हैं ।

हि. भा.—ब्रह्मा के कल्प के द्वितीयाध (पराध) में छः मनु गत हो गये । वर्तमान मनु के सत्ताइस महायुग बीत गये, अष्टादशवें युग के सत्य युगादि तीन युग चरण बीत गये, शकान्त में कलियुगादि से ३१७६ इतने वर्ष बीत गये, गत छः मनुष्यों के आदि में मद्य में और अन्त में जो मनु सन्धि है उनके साथ, शकान्त में १६७२६४७१७६ इतने सौरवर्ष बीत गये, पूर्व कथित गनमनु-गतमहायुगादियों के योग करने से आचार्य पठिताङ्क आता है या नहीं इसके लिए गणित दिखलाते हैं ।

$$\begin{aligned} & \text{लोकोक्ति के अनुसार ६ मनु + ७मनुसन्धि + २७ युग + कृतादि युगचरणत्रय +} \\ & ३१७६ = ६मनु + ७मनुस + २७युग + (युग-कलिवरण) + ३१७६ \\ & = ७ \times ७१५ + ७ \times ४ \times ४३२००० + २७ \times ४३२०००० + (४३२०००० - \\ & \quad ४३२०००) + ३१७६ \\ & = ४२६यु \times २८ \times ४३२००० + २७ \times ४३२०००० + (४३२०००० - \\ & \quad ४३२०००) + ३१७६ \\ & = ४२६ \times ४३२०००० + १२०६६००० + ११६६४०००० + ३८८८०००० + \\ & \quad - १७६ \\ & = १८४०३२०००० + १२०६६००० + ११६६४०००० + ३८८८०००० + ३१७६ \\ & = १६७२६४७१७६ = \text{आचार्य पठिताङ्क ।} \end{aligned}$$

यहाँ कहने का अभिप्राय यह है कि आर्यभट और वटेश्वराचार्य को छोड़कर जितने भारतीय ज्योतिषाचार्य हुए हैं उन्होंने ग्रहादि चार साधन शक ही से किये हैं, कलियुगादि से ३१७६ एतन्मितवर्षान्त में शक वर्षारम्भ हुआ यह बात भारतीय गणक समाज में प्रसिद्ध है, इपलिय कलादि से शकान्त तक जितने सौरवर्ष बीते हैं इसी बहुत आवश्यकता प्रतीत हुई अतः उक्त गनमनु, मनुसन्धि आदि का योग कर आचार्य ने उपरिलिखित अङ्क पठित

किये हैं, इसके बिना ग्रहगंगादि. का साधन हो ही नहीं सकता । भास्कराचार्य भी 'याताः षड्मनवो युगादि भनितानि' इत्यादि से ब्रह्मगुप्तोक्त के अनुरूप ही करते हैं । इति ॥२६-२७॥

ग्रहनक्षत्रोत्पत्तिर्ब्रह्मदिनादौ दिनक्षये प्रलयः ।

यस्मात्कल्पस्तस्माद् ग्रहगणिते कल्पयाताब्दाः ॥ २८ ॥

वा. भा.—ग्रहाणां नक्षत्राणां च सृष्टिः ब्रह्मदिनादौ कल्पादौ, दिनक्षये प्रलयः कल्पान्ते ग्रहनक्षत्राणां पुनरपि विनाशः, यस्मादेवं तस्मात्कल्प एव ग्रहगणिते उपयुज्यते । न ततोत्राक् नवाग्रतो ग्रहगणयिनुरभावादित्यर्थः । द्वितायार्धे पठऽन्येषां यस्मात्कल्पस्तस्माद् ग्रहगणितं यत एव कालात्कल्पः प्रवृत्तस्तत एव कालात् ग्रहगणितमपि प्रवृत्तमित्यर्थः । कल्पयाताब्दाः इत्युत्तरत्र संवत्स्रं भविष्यतीति यदुक्तं प्राक्कल्पयाताब्दास्तानाह ॥

वि. भा.—ग्रहश्च नक्षत्राणि च ग्रहनक्षत्रं तस्योत्पत्तिः सृष्टिः ब्रह्मदिनादौ कल्पादौ भवति । तथा दिनक्षये ब्रह्मदिनावसाने कलान्त इत्यर्थः । तेषां ग्रहनक्षत्राणां प्रलयः नाशो भवति । अर्थादेतदुक्तं भवति । कल्पप्रमाणं ब्रह्मणो दिनं भवति । “कल्पो ब्राह्ममहः प्रोक्त”मिति सूर्यसिद्धान्तोक्तेः । तत्प्रमाणा तस्य रात्रिः स्यात् । “सर्वान् पदार्थान् संहृत्य ब्रह्मा शेते” इत्याप्तवचसा ब्रह्मा स्वदिनादौ कल्पादौ सृष्टिं रचयति । कल्पावसानेऽर्थाद्रि कल्पे सर्वान् संगृह्य शेते । अतः सृष्टिकल्प एव ग्रहनक्षत्रादयो वर्तन्ते । कल्पावसाने च सर्वाणि तानि ग्रहनक्षत्राणि तस्मिन् विलीयन्ते । “अव्यक्ताद्व्यक्तयः सर्वाः प्रभवन्त्यहरागमे । रात्र्यगमे विलीयन्ते तत्रैवाव्यक्तसंज्ञके” इति भगवद्वाक्यम् ।

अथ यस्मात्कारणात् कल्पोऽस्त्यत्र कल्पशब्देन दिनकल्प एव विवक्षितः । अस्मिन्नेव ग्रहादीनां सञ्ज्ञावात् । विद्यमानेषु तेषु ग्रहादिषु तेषां गत्यावगमो भवितुमर्हति । अतएव भास्कराचार्या अपि “यतः सृष्टिरेषां दिनादौ दिनान्ते लयस्तेषु सत्स्वेव तच्चारचिन्ता” इति निजे सिद्धान्तशिरोमणी प्रोचुः । तस्मात् कारणात् ग्रहगणिते ग्रहादीनां गत्यावगमे कल्पयाताब्दाः साध्यन्त इत्यर्थः । नैयमार्या म० म० सुभाकरद्विवेकिसकितपुस्तके समुपनभ्यत इति म० म० मुरलीधरभा लक्षादवगम्यते । किन्तु मुनीश्वरेण मरीच्यभिधयां शिरोमणौ निजटीकायां बह्मादरेण सन्निवेशिता समाहृता च । अतएव अस्यैव दिनकल्पस्य प्रयोजनं भवति तान्यस्येति । ग्रन्थकाराशयः ॥२८॥

हि. भा.—एक कल्प के बराबर ब्रह्मा का एक दिन होता है। ऐसा आगमशास्त्र का मत है । सूर्यसिद्धान्त का वचन है कि “कल्पो ब्राह्ममहः प्रोक्तम्” एक कल्प ब्रह्मा का दिन कहा

जाता है उतनी ही उनकी रात्रि होती है । अपने दिनादि में ब्रह्मा सब ग्रहनक्षत्रों की रचना करते हैं और दिनावसान में अपने सब को संहार करके सोते हैं । ऐसा ही भगवान् का वाक्य है । “अव्यक्ताद्व्यक्तयः सर्वाः प्रभवन्त्यहरागमे । रात्र्यागमे प्रलीयन्ते तत्रैवाव्यक्तसंज्ञके ॥” दिन के आरम्भ में अव्यक्तरूप ब्रह्म से यह सब व्यक्त (जगतरूप में) निकलते हैं और रात्र्यारंभ में सब उसी अव्यक्त ब्रह्म में लीन हो जाते हैं । इसलिए यहां आचार्य का कथन है कि दिनकल्प मे ही ग्रहों के रहने का कारण उनकी गति होती है और उसके साधन के लिये यही दिनकल्प से वर्षमान की आवश्यकता है, अन्यकल्पवर्ष की आवश्यकता नहीं है । यह ग्रन्थकार का आशय है ॥ २८ ॥

अब अहर्गणानयन कहते हैं

हि. भा.—कल्पादि से जो गत वर्ष संख्या १६७२६४७१७६ है उसको बारह से गुणा देना, गत चैत्रादि मास संख्या जोड़कर जो हो उसको दो स्थान में स्थापित करना । एक स्थान में युग पठित अधिमास संख्या से गुणाकर युग पठित सौर मास संख्या से भाग देने से जो लब्धाधिमास हो उसको द्वितीय स्थान में स्थापित फल में जोड़कर जो हो उसको तीस से गुणा कर शुक्ल प्रतिपदादि से गत तिथि संख्या जोड़कर जो फल हो उसको दो स्थान में स्थापित करना, एक स्थान में उसको युगपठित अवमदिनों से गुणा कर युगपठित चान्द्र दिनो से भाग देने से जो लब्धि हो उसको (गतावमदिन) द्वितीय स्थान स्थित पूर्व फल में घटाने से रविसावनाहर्गण होता है; रवि से आरम्भ कर अहर्गण की प्रवृत्ति होती है । इसीलिये आचार्य पञ्च में ‘अकादिः’ कहते हैं ॥ ३०-३१ ॥

शाकवर्ष-सप्तमास तिथि इन सबों के ज्ञान से ग्रहगण का ग्रहणन करते हैं। 'बल्य-परर्धे मनवः षट्कस्य गताः' इत्यादि आचार्यों के श्लोक से सृष्ट्यादि से गतवर्षान्त तक गत वर्ष संख्या विदित है, सृष्ट्यादि से चान्द्रवर्षतुल्य दान देने से जो दानान्त बिन्दु होता है वह किसी चैत्रामान्त बिन्दु ही पर होता है; फिर गत चैत्रामान्त से इष्टतिथ्यन्त पर्यन्त जो चान्द्रदिन संख्या है तत्संख्यक सौर दिन संख्या (इष्ट तिथि संख्यक सौर दिन संख्या) गत मेषादि से दान दिया वह सौरदानान्तबिन्दु इष्ट तिथ्यन्त से आगे होता है क्योंकि गमेषादि बिन्दु गतचैत्रामान्त से आगे है फिर दानान्त बिन्दु का चान्द्रवर्षान्त से (दानान्त चैत्रामान्त से) इष्ट तिथि तुल्य चान्द्र दिन दिया तब वह दानान्तबिन्दु गतवर्षान्त से पहले ही कहीं इष्ट तिथ्यन्तममबिन्दु ही में होता है। क्योंकि, चान्द्रदिन < सौरदि. तब सृष्ट्यादि से सौरवर्षादि संख्या और चान्द्रवर्षादि संख्या-समान ही दान दिया क्योंकि सृष्ट्यादि से गतवर्षान्त पर्यन्त सौर वर्ष संख्या जो है तत्संख्यक ही सृष्ट्यादि से चान्द्रवर्ष दिये उससे आगे फिर गत मेषादि से सौरान्तपर्यन्त इष्टतिथितुल्य सौर संख्या जो है उतने ही दानान्त चान्द्रवर्षान्त से इष्ट तिथि तुल्य चान्द्र दिन दिया, अतः इन दोनों (सृष्ट्यादि से सौरदानान्त बिन्दुपर्यन्त चान्द्रवर्षादि संख्या जो है तत्संख्यक ही सृष्ट्यादि से इष्टतिथ्यन्त सम दानान्त बिन्दु पर्यन्त चान्द्रवर्षादि संख्या) के अन्तर (इष्टतिथ्यन्तसमदानान्तबिन्दु से सौरान्तबिन्दुपर्यन्त) चान्द्रजातीय सावयवाधिमास है, उनमें इष्टतिथ्यन्तसमदानान्त बिन्दु से इष्टतिथ्यन्त पर्यन्त पूरा अधिमास है उसके बाद, (इष्टतिथ्यन्त से सौरान्त तक) अधिशेष है। सौरान्त में जो चान्द्र है उनका और सौरसंख्यक चान्द्र का अन्तर सावयवाधिमास जो है वही सौरान्त में जो सौर है उनका और उस सौरान्तःपाति चान्द्रसंख्यक सौर का अन्तर है, दोनों में संख्या की तुल्यता ही है किन्तु चान्द्रात्मक अधिमास सौरान्त से पहले और सौरात्मक अधिमास आगे होता है। इन दोनों में यहाँ पहला ही अधिमास लेना चाहिये। इसलिए उसका ग्रहणन करते हैं।

$$\frac{\text{बल्यधिमास} \times \text{इष्टसौर}}{\text{कलासौर}} = \text{गताधिमास} + \frac{\text{अधिशेष}}{\text{क.सौर}} \text{ इस तरह करके यहाँ अधिशेष को}$$

त्याग देना क्योंकि इष्ट तिथ्यन्त से सौरान्त तक अधिशेष ही है, इष्टाधिमाससंख्या (गताधिमाससंख्या) को तीस से गुणकर जो हो गताधिदिन उसमें इष्टसौर दिन संख्या जोड़ने से जो इष्ट तिथ्यन्त में चान्द्राहर्गण होता है। तब कलाचान्द्रदिन में कल्पावमदिन पाते हैं तो इष्टचान्द्रदिन (आनीतचान्द्राहर्गण) में क्या इस अनुगत से अवमशेष सहित

$$\text{गतावमदिन आता है } \frac{\text{कलावम} \times \text{इष्टचान्द्रदिन}}{\text{कलाचान्द्रादन}} = \text{गतावमदिन} + \frac{\text{अवमशेष}}{\text{कलाचान्द्रदिन}} \text{ इन अवमशेष सहित गतावमदिन को चान्द्राहर्गण में घटाने से तिथ्यन्त में सावनाहर्गण होता है चान्द्रा-}$$

हर्गण-गतावमदिन — $\frac{\text{अवमशेष}}{\text{कलाचान्द्रदिन}}$ परन्तु तिथ्यन्त और सूर्योदय के मध्य में अवमशेष है इसलिए तिथ्यन्त कालिक सावनाहर्गण में अवमशेष को जोड़ने से सूर्योदयकालिक सावनाहर्गण

$$\text{होता है, चान्द्राहर्गण} = \text{गतावमदिन} + \frac{\text{अवमशेष}}{\text{कलाचान्द्रादन}} + \frac{\text{अवमशेष}}{\text{कलाचान्द्रदिन}} = \text{चान्द्राहर्गण} =$$

गतावमदि = तिथ्यन्तकालिक सावनाहर्गण + $\frac{\text{अवमशे}}{\text{कल्पचादि}}$ = सूर्योदयकालिक सावनाहर्गण ।

अहर्गण के दिन निश्चित रहने के कारण अहर्गण में सात से भाग देने से जो शेष रहता है तत्तुल्य रव्यादि दिन होता है क्योंकि कल्पादि में रविवार दिन था इसलिए रवि ही से गणना करनी चाहिये, इससे आचार्योक्त उपपन्न हुआ । आनीत अहर्गण मध्यम सावनाहर्गण है, क्योंकि इसके आनयन में अनुपात से काम लिया गया है, सिद्धान्तशिरोमणि में भास्कराचार्य ने भी “कथितकल्पगतोऽर्कसमागणः” इत्यादि से इसी तरह आनयन किये हैं, इति ॥३०-३१॥

$$\therefore \text{स्य}^३ \frac{१}{३} \text{ जि} = १८६६४७४७८$$

$$\therefore \frac{\text{स्य}^३ \frac{१}{३} \text{ जि}}{\text{त्रि}} = ८६६४७४७८$$

$$\therefore \text{परमोदयान्तरासवः} = २' = २\sqrt{} = १४\sqrt{}'$$

$$\text{षड्भिर्भक्ताः पलानि} = २५,$$

अत्र भास्कराचार्येण २६ पलानि गृहीतानि । भास्करोक्तमुदयान्तरं व्यर्थं दुराग्रहेण प्रखण्डितं कमलाकरेण । तदर्थं तत्त्वविवेको द्रष्टव्यः ।

एतद्वलेन “परमोदयान्तरज्ञानेनाहर्गणानयनं कथं भवेदेतस्य विलक्षणप्रश्न-स्योत्तरसिद्धिर्भवति” यथा परमोदयान्तरज्ञानेन पूर्वोक्तसूत्र ‘त्रिज्येषु वेदांशगुणने-त्यादि’ द्वारा तत्कालीनभुजांशज्ञानं भवेत्ततो “निरग्रचक्रादपि कुट्टकेनेत्यादि विलोमेन” अहर्गणज्ञानं सुखेनैव भवेदिति, उदयान्तरखण्डनं कमलाकरेण कृतं तत्समी-चीनं नास्ति तथाऽन्येऽपि बहवो विशेषाः सन्त्युदयान्तरसम्बन्धे तेऽत्रविस्तृतिभयात् लिख्यन्त इति ॥ ३१ ॥

अब ग्रहानयन कहते हैं

हि. भा.—ग्रहण को दृष्टग्रह के कल्प में पठित भगण से गुण कर कल्प सावन (कल्प कुदिन) से भाग देने से फल भगणादि मध्यम ग्रह लङ्काक्षितिजोदय (लङ्का सूर्योदय) कालिक होते हैं ॥ ३१ ॥

उपपत्ति

$$\frac{\text{कल्प ग्रहभगण} \times \text{ग्रहगण}}{\text{कल्पकुदिन}} = \frac{\text{ग्रहभ}}{\text{ककु}} + \frac{\text{भगणशे}}{\text{ककु}} \text{ यहाँ ग्रहगण के मध्यम सावनदिन समूह}$$

रूप होने के कारण उस पर से पूर्वोक्तानुपातद्वारा जो भगणादि मध्यम ग्रह आते हैं, वे भी मध्यम

सावनान्त बिन्दुक ही होंगे, $\frac{\text{वर्षान्तःपातिस्पष्टसावनयोग}}{\text{वर्षान्तःपातिस्पष्टसावनसं}} = \text{मध्यमसावन, वर्षान्तःपाति,}$

स्पष्टसावनयोगसम्बन्धिनाक्षत्र = वर्षान्तःपातिस्पष्टसावनसंख्या + १ नाक्षत्र इसलिए

$$\frac{\text{वर्षान्तःपातिस्पष्टसावन सं १ नाक्षत्र}}{\text{वर्षान्तःपातिस्पष्टसावनसं}} = १ ना + \frac{१ ना}{\text{वर्षान्तःपातिस्पष्टसावनसं}} = १ ना +$$

$$\frac{२१६०० \text{ अशु}}{\text{वर्षान्तःपातिस्पष्टसावनसं}} \text{ परं } \frac{२१६०० \text{ कला}}{\text{वर्षान्तःपातिस्पष्टसावनसं}} = \text{मध्यगतिक; अतः मध्यमगति-}$$

$$\text{कलासमासु} = \frac{२१६०० \text{ अशु}}{\text{वर्षान्तःपातिस्पष्टसावनसं}}$$

इसलिए मध्यमसा = १ ना + मध्यगतिकलासमासु, लेकिन कला समान अशु नाडीवृत्त ही में होती है इसलिए उक्त ग्रह नाडीवृत्त ही में चालनीय है, यह सिद्ध हुआ। इसलिए अपने कल्प पठित भगण से पूर्वोक्तानुपात से जो मध्यमग्रह आते हैं, वे क्रान्ति वृत्तीय भुजांशतुल्य नाडीवृत्तीय चाप के अग्रबिन्दुक होते हैं अतः 'दशशिरः पुरि मध्यम भास्करे क्षितिज सन्निधिगे सति मध्यमः' भास्कराचार्य कहते हैं, गोल सन्धि बिन्दु से पूर्वाभिमुख चालित समान गति वेगक नाडीवृत्तीय और क्रान्तिवृत्तीय मध्यमार्कों में जब नाडीवृत्तीय मध्यमार्क लङ्काक्षितिज में होते हैं तब क्रान्तिवृत्तीय मध्यमार्क पदवश से क्षितिज से ऊपर और नीचे (भुजांश और विषुवांश के अन्तर पर) होते हैं; दोनों ग्रहोदयों के अन्तर को उदयान्तर भास्कराचार्य कहते हैं परमोदयान्तर भी अत्र ही होता है इसलिए भास्कराचार्य 'क्षितिज सन्निधिगे' कहते हैं; इस अन्तर (उदयान्तर) को ब्रह्मगुप्त शून्य मानते हैं इसलिए 'लङ्कायां भास्करोदयिकः' कहते हैं यहाँ भास्कराचार्य का कथन ही ठीक है उदयान्तर नहीं मानना अनुचित है, भास्कराचार्य ने एक उदयान्तर रूप विलक्षण वस्तु दिखलाकर अपने अद्भुत पाण्डित्य का परिचय दिया है इस विषय पर ज्योतिषिक लोग निष्पक्ष बुद्धि से विचार करें ॥ ३२ ॥

अब प्रसङ्ग से उदयान्तर के सम्बन्ध में कुछ विचार करते हैं

क्रान्तिवृत्त में जहाँ पर मध्यम रवि है उसके ऊपर ध्रुवप्रोतवृत्त (निरक्षक्षितिज) करने से नाडीवृत्त में जहाँ लगता है, वहाँ से गोलसन्धि पर्यन्त नाडीवृत्तीयचाप विषुवांश या मध्यमरविगतिकलोत्पन्नासु है, नाक्षत्र षष्टि (६०) घटी में मध्यमरविगतिकलोत्पन्नासु को

जोड़ने से स्पष्टसावन होता है, गोलसन्धि बिन्दु को केन्द्र मानकर क्रान्तिवृत्तीयमध्यमरवि भुजांश व्यासार्धवृत्त करने से नाडीवृत्त में जहाँ लगता है वहाँ से गोल सन्धि बिन्दु तक नाडी-वृत्त में मध्यमरविगतिकलातुल्यासु है, नाक्षत्र षष्टि (६०) घटी में मध्यमरविगतिकला तुल्यासु को जोड़ने से मध्यम सावन होता है। इन दोनों (स्पष्टसावन और मध्यम-सावन) के अन्तर करने से मध्यमरविगतिकलातुल्यासु-मध्यमरविगतिकलोत्पन्नासु = उदयान्तरासु, एतत्सम्बन्धिग्रहगति प्रमाण लाते हैं जैसे यदि अहोरात्रासु में ग्रहगति कला पाते हैं तो उदयान्तरासु में क्या इस अनुपात से उदयान्तरासु सम्बन्धिनी ग्रहगति आती है

ग्रहगतिकला × उदयान्तरासु

अहोरात्रासु = उदयान्तरासु सम्बन्धिनी ग्रहगति, इसको ग्रहगणोत्पन्न ग्रह में

घटाने से और जोड़ने से निरक्षक्षितिजस्थ (क्रान्तिवृत्तस्थ मध्यमरविगत ध्रुवप्रोतवृत्त नाडीवृत्त सम्पात बिन्दुक) ग्रह होते हैं। इसी विषय को सिद्धान्त शिरोमणि में भास्कराचार्य 'मध्यार्क भुक्ता असवो निरक्षे ये ये च मध्यार्ककला 'समाना' इत्यादि से कहते हैं। लेकिन उदयान्तरासु के मध्य में भी ग्रह की कुछ गति होगी। उस गति का ग्रहण भास्कराचार्य नहीं किये हैं, इसलिए पूर्व प्रदर्शित उदयान्तरासुसम्बन्धिनी ग्रहगतिस्मन्ध से जो निरक्षक्षितिजोदय कालिक ग्रह लाये हैं सो ठीक नहीं है इसलिए भास्करोक्त उदयान्तरानयन ठीक नहीं है, यह सिद्ध हुआ।

अब वास्तव उदयान्तर साधन करते हैं

वास्तव उदयान्तर प्रमाण = य मानते हैं, इसी से औदयिक ग्रह होते हैं, इस उद-यान्तर काल में ग्रह की जो गति होती है, तदुत्पन्नासु करके संस्कृत भास्करोक्त उदयान्तर वास्तव उदयान्तर होता है। यथा यदि अहोरात्रासु में रविगतिकला पाते हैं तो वास्तवोदयान्तरा (य) सु में क्या इस अनुपात से वास्तवोदयान्तरासु सम्बन्धिनी रविगति कला आती है,

रविगतिकला × य

अहोरात्रासु

= एकासुजरविग × य, फिर अनुपात करते हैं यदि राशि कला (१८००) में

उस राशि का उदयासु पाते हैं तो वास्तवोदयान्तरासुसम्बन्धिनी रविगतिकला में क्या इस अनुपात से तत्सम्बन्धि असु प्रमाण आता है राश्युदयासु × वास्तवोदयान्तर संरविगतिक = १८००

राश्युदय × रविगतिकला × य

१८०० × अहोरात्रासु

= एकासुजरविगति × १ कलोत्पन्नासु × य... (१)

∴ राश्युदय × १

१८००

= १ कलोत्पन्नासु, भास्करोक्तोदयान्तर में (१) इसको संस्कार करने से

वास्तव उदयान्तर होता है, अतः भास्करोक्तोदयान्तर ± एकासुजरविग × १ कलोत्पन्नासु × य = य = पूर्वोदयान्तर ± एकासुजरविग × १ कलोत्पन्नासु × य समशोधन करने से य ± एकासुजरविग × १ कलोत्पन्नासु × य = पूर्वोदयान्तर = य (१ ± एकासुजरविग × १ कलोत्पन्नासु)

∴ य = पूर्वोदयान्तर

१ ± एकासुजरविग × १ कलोत्पन्नासु (क)

यहां इनगति=सूर्यगति, सूर्यगतिकलासम्बन्ध से वास्तव उदयान्तर साधन किया गया है, अपनी-अपनी गति के सम्बन्ध से अन्य ग्रहों का साधन उसी तरह से होता है।

(क) इससे 'एकाकुजेनगतिसङ्गुणितैकलिप्तोत्पन्नासु राश्वुदययुक्तविहीनितेन' इत्यादि संस्कृतोपपत्तिस्थ म० म० पण्डित सुधाकर द्विवेदी जी का सूत्र उपपन्न होता है।

अब उदयान्तर का परमत्व कहाँ होता है, विचार करते हैं

भुजांश और विषुवांश का अन्तर उदयान्तर है; इसलिए उदयान्तरज्या = (भु—वि)

चापयोरिष्टयोः इत्यादि से $\frac{\text{ज्याभु} \times \text{कोज्यावि} - \text{ज्यावि} \times \text{कोज्याभु}}{\text{त्रि}} = \text{उदयान्तरज्या},$

यतः $\frac{\text{कोज्याभु} \times \text{त्रि}}{\text{द्वु}} = \text{कोज्यावि}$

तथा $\frac{\text{पद्य} \times \text{ज्याभु}}{\text{द्वु}} = \text{ज्यावि},$ उदयान्तरज्या स्वरूप में उत्थापन से

$\frac{\text{ज्याभु} \times \text{कोज्याभु} \times \text{त्रि} - \text{पद्य} \times \text{ज्याभु} \times \text{कोज्याभु}}{\text{त्रि. द्वु}} = \frac{\text{ज्याभु} \times \text{कोज्याभु} (\text{त्रि} - \text{पद्य})}{\text{त्रि. द्वु}}$

$= \frac{\text{ज्याभु} = \text{कोज्याभु} \times \text{ज्याजिउ}}{\text{त्रि. द्वु}} = \text{उदयान्तरज्या},$ ज्याजिउ = जिनांशोत्क्रमज्या।

यहां हर और भाज्य को 'त्रि × पद्य' इससे गुण देने से

$\frac{(\text{त्रि} + \text{पद्य}) (\text{ज्याभु} \times \text{कोज्याभु} \times \text{ज्याजिउ})}{\text{त्रि. द्वु. } (\text{त्रि} + \text{पद्य})}$

$= \frac{(\text{त्रि. ज्याभु. कोज्याभु} + \text{ज्याभु. कोज्याभु. पद्य}) \text{ ज्याजिउ}}{\text{त्रि. द्वु } (\text{त्रि} + \text{पद्य})}$

$= \frac{(\text{ज्याभु. कोज्यावि} + \text{ज्यावि. कोज्याभु}) \text{ ज्याजिउ}}{\text{त्रि. } (\text{त्रि} + \text{पद्य})}$

$= \frac{\text{ज्या } (\text{भु} + \text{वि}) \text{ ज्याजिउ}}{\text{त्रि} + \text{पद्य}} = \text{उदयान्तरज्या} \dots (१)$

(१) इससे "विषुवांशभुजांशयोगजीवा" इत्यादि संस्कृतोपपत्तिस्थ म० म० पण्डित सुधाकर द्विवेदी जी का सूत्र उपपन्न होता है ॥

(१) इसमें ज्याजिउ, त्रि + पद्य इन दोनों गुणक और हर के स्थिरत्व के कारण जहाँ ज्या (भु + वि) इसका परमत्व होगा वहीं पर उदयान्तरज्या का परमत्व होगा अर्थात् उदयान्तर का परमत्व होगा। परन्तु ज्या त्रिज्या से अधिक नहीं होती है इसलिए

जहां ज्या (धु + वि) = त्रि होती है, वहीं पर उदयान्तर का परमत्व होता है, यह सिद्ध हुआ । गोलसन्धि (नाड़ीवृत्त और क्रान्तिवृत्त के सम्पात) में भुजांश और विषुवांश के अभाव से उन दोनों के अन्तररूप उदयान्तर का अभाव होता है तथा अयन सन्धि में मध्यमार्क के रहने से भुजांश और विषुवांश के नवत्यंश के बराबर होने से दोनों के अन्तररूप उदयान्तर का अभाव होता है, यह सिद्ध हुआ ।

अब परमोदयान्तरकालीन भुजांश और विषुवांश के साधन करते हैं

पहले सिद्ध हुआ है कि जब भुजांश और विषुवांश की योगज्या त्रिज्या के बराबर होती है अर्थात् भुजांश और विषुवांश का योग नवत्यंश के बराबर होता है तब उदयान्तर का परमत्व होता है, इसलिए परमोदयान्तर में भुजांश + विषुवांश = ९०, और उस अवस्था में भुजांश और विषुवांश का अन्तर = परमोदयान्तर, तब संक्रमण गणित से

$$\frac{९० + \text{परमोदयान्तर}}{२} = ४५ + \frac{\text{परमोदयान्तर}}{२} = \text{परमोदयान्तर कालीन भुजांश}$$

तथा

$$\frac{९० - \text{परमोदयान्तर}}{२} = ४५ - \frac{\text{परमोदयान्तर}}{२} = \text{परमोदयान्तर कालीन विषुवांश ।}$$

अथवा

धु = ध्रुव । अ = क्रान्तिवृत्त में मध्यमार्क, गो = गोलसन्धि, गोप्र = भुजांश, गोन = विषुवांश नाड़ीवृत्त में गोप्र भुजांश तुल्य गोप काटकर पप्र वृत्त बना दीजिये, गो बिन्दु से पप्र के ऊपर गोच लम्ब वृत्त कर दीजिये, गोन + गोप = विषुवांश + भुजांश यह जब नवत्यंश के बराबर होता है तब ही उदयान्तर का परमत्व होता है, इसलिए उदयान्तर के परमत्व में गोन + गोप = विषुवांश + भुजांश = ९० अनप चापीय जात्यत्रिभुज में पनकोटि = ९० अतः पप्रकणोंजपि = ९०, तदा अच = चप = ४५ (अगोपचापीय त्रिभुज के समद्विबाहुकत्व के कारण), < अचगो = ९०, < अगोन = जिनांश < अगोप = १८० - जिनांश, < अगोच = $\frac{< अगोप}{२} = \frac{१८० - जिनांश}{२}$ = $९० - \frac{\text{जिनांश}}{२}$ = जिनांशार्ध को तब गोचपचापीय जात्यत्रिभुज में अनुपात से $\frac{\text{त्रि} \times \text{ज्या } ४५}{\text{जि कोज्या } २} = \text{ज्या गोप} = \text{परमोदयान्तर कालीन भुजज्या}$, इसके चाप करने से परमोदयान्तर कालीन भुजांश हुआ, कोज्या $\frac{\text{जि}}{२} = \text{जिनांशार्धकोटिज्या}$, इससे संस्कृतोपपत्तिस्थ 'त्रिज्येषु वेदांशगुणेन ताडिता' इत्यादि सूत्र उपपन्न हुआ । यहाँ संस्कृतोपपत्तिस्थ (क) क्षेत्र देखिये ॥

उपर्युक्त उपपत्ति के बल से “परमोदयान्तर ज्ञान से ग्रहगण ज्ञान कैसे होगा, इस विलक्षण प्रश्न का उत्तर सुलभ ही होता है” जैसे परमोदयान्तर ज्ञान से उपर्युक्तोपपत्ति द्वारा तत्कालीन भुजांश ज्ञान हो जायगा तब ‘निरग्रचक्रादपि कुट्टकेन’ इत्यादि के विलोम से ग्रहगण ज्ञान सुलभ हो जायगा, उदयान्तर का खण्डन सिद्धान्ततत्त्वविवेक में कमलाकर जी ने किया है सो ठीक नहीं है, उदयान्तर के सम्बन्ध में बहुत अन्य विशेष विषय है जो विस्तृति भय से नहीं लिखते हैं इति ॥३२॥

इदानीं स्वसिद्धान्तप्रगणसार्थमार्यामाह—

आनयति दिवसवारं स्मृत्यविरोधेन मध्यमग्रहा वा ।
ब्राह्मादन्यस्तन्त्रैरार्यभटाद्यैर्न कश्चिदपि ॥ ३३ ॥

आचार्य अपने आनयन की प्रशंसा करते हैं

हि. भा.—स्मृतिशास्त्रानुकूल हमारे तन्त्र ही से ज्योतिषिक लोग ग्रहगण और
मध्यग्रहों को लाते हैं, स्मृतिशास्त्र प्रतिकूल आर्यभटादि आचार्य प्रणीत तन्त्रों से कोई भी
ग्रहगण-मध्यग्रहों को नहीं लाते हैं ॥३३॥

इदानीं येऽर्धरात्रे वारप्रवृत्तिमिच्छन्ति तान्प्रत्याह

जगति तमोभूतेऽस्मिन्सृष्ट्यादौ भास्करादिभिः सृष्टैः ।
यस्माद्दिनप्रवृत्तिर्दिनवारोऽर्कोदयात्तस्मात् ॥ ३४ ॥

वा. भा.—अयमर्थः सृष्ट्यादौ यत्रैव काले भास्करोदये ग्रहाः सृष्टास्तत एव कालादुद्वापरप्रवृत्तिः । यतः प्रथमं दिनं पञ्चाद्वात्रिः । षट्प्रहराश्च वाररहिता भवन्तीत्येतदपि न शक्यते वक्तुम् । सृष्ट्यादेः पूर्वार्धरात्रे चेत्तदपि न यस्मात् “सति धर्मिणि-धर्माश्चिन्त्यन्ते” इति यावान्नाकोदयः सृष्टस्तावदियं रात्रिरयं दिवसः इति कथमुच्यते । सृष्टेः प्राक् सर्वमेव तमोभूतमासीत् । अत्र भगवान्मनुः—आसीददं तमोभूतम-प्रजातमलक्षणम् । अप्रतर्क्यमनाष्टुष्टं प्रसुप्तमिव सर्वतः इति । अत्र लंकासमयाम्योत्तर रेखापेक्षयोच्यते । अर्धरात्रे वारप्रवृत्तिर्न भवति अन्यथा रोमके सर्वदैव वार-प्रवृत्तिरर्धरात्रेऽप्यत्रास्तमयेऽप्यत्रमध्याह्नेऽप्यत्रोष्टकाले इत्यादि योज्यम् ।

वि. भा.—यस्मात् कारणात्—अस्मिन् तमोभूते प्राकृतिकप्रलये सूर्यादीना-मभावादन्धकारमये जगति (संसारे) ब्रह्मणा सृष्टेः (रचितैः) भास्करादिभिः (सूर्याद्यैः) सृष्ट्यादौ (सृष्ट्यादिकाले) दिनप्रवृत्तिर्जातिऽथसृष्टेर्भास्करादिभि-रित्यनेन सर्वप्रथमं सूर्यस्यैव रचना कृता तत्समय एव वारप्रवृत्तिरभवत्—तस्मात् कारणादकोदयादेव (सूर्योदयादेव) दिनवारो ज्ञातव्य इति, आचार्योत्तमिदं तदैव समीचीनं भवितुमर्हति यदा प्राकृतिकप्रलये सूर्यस्य लयो भवेत् परं ‘सूर्याचन्द्रमसौ धाता यथा पूर्वमकल्पयदिति’ वेदोक्त्या सूर्यस्य नित्यत्वं सिद्धयति, सृष्ट्यादौ ब्रह्मणा किञ्चित्प्रकाशवति सूर्येऽतिप्रकाशवर्धनार्थमेकः सीसरूपपदार्थो निवेशितो यद्द्वारा सूर्येऽतीवप्रकाशः परिलक्ष्यते, ‘सूर्य आत्माजग-तस्तस्थुषश्चेति’ वेदोक्त्या ब्रह्मा सूर्यस्य पुत्रोऽस्तीति सिद्धयति तर्हि ब्रह्मणा सूर्यस्य-रचना कथं भवेत् पुत्रद्वारा पितुः सृष्टेरभावात् सूर्यरचनासम्बन्धे सूर्येण सह ब्रह्मणः केवलमेतावानेव सम्बन्धो यच्च सृष्ट्यादौ किञ्चित्प्रकाशवति सूर्ये प्रकाश-वर्धनार्थमुपरि मया प्रदर्शित इति । अन्येषां मते—सृष्टेरित्यत्र सूर्यादीनां नवीना सृष्टिरासीदिति न भ्रमितव्यम् । न चात्र पितापुत्रयोः सम्बन्धोऽपेक्ष्यते येन सृष्टौ वैषम्यमापद्येत । अत्र सृजनं पार्थिवजीवानां भवति । तथा सति सृष्ट्यादौ नित्याम्बरवासिनां तेषां सूर्यादीनां प्रथमं संदर्शनं भवेदित्येव सृष्टिपदस्य तात्पर्यम् । “भूगतानां विनाशः स्यान्नो नित्याम्बरवासिनामिति कमलाकरोक्तेः” । सूर्य आत्मा जगत्तस्तस्थुषश्चेति वेदे उक्तः ॥३४॥

अब दिन प्रवृत्ति को कहते हैं

हि. भा.—जिस कारण से प्राकृतिक प्रलय में सूर्यादिग्रहों के अभाव से अन्धकार-मय इस संसार में ब्रह्मा ने सूर्यादि की रचना की, इससे सृष्ट्यादि काल में दिन प्रवृत्ति हुई अर्थात् ब्रह्मा ने सबसे पहले सूर्य की रचना की, उसी समय वार प्रवृत्ति हुई, इस कारण से सूर्योदय ही से दिनवार समझना चाहिये,

आचार्य का यह कथन तब ही ठीक हो सकता है जब कि प्राकृतिक प्रलय में सूर्य का लय हो, लेकिन ‘सूर्याचन्द्रमसौ धाता यथापूर्वमकल्पयत्’ इस वेदोक्ति से सूर्य निरग्न है यह

सिद्ध होता है । सृष्ट्यादि काल में किञ्चित्प्रकाशवान् सूर्य में अतिशय प्रकाश बढ़ाने के लिये ब्रह्मा ने एक सीसा रूप पदार्थ सूर्य मण्डल में दे दिया जिसके द्वारा सूर्य-मण्डल में अतीव प्रकाश फैलने की शक्ति हुई, 'सूर्य आत्मा जगतस्तस्थुषश्च' इस वेदोक्ति से ब्रह्मा सूर्य के पुत्र सिद्ध होते हैं तब पुत्र द्वारा पिता की सृष्टि कैसे हो सकती है इससे सिद्ध होता है कि ब्रह्मा द्वारा सूर्य की सृष्टि नहीं होती है, सूर्य रचना के विषय में सूर्य के साथ ब्रह्मा का सम्बन्ध वही है जो पहले सूर्य के प्रकाश बढ़ने के लिये कहा गया है ॥३४॥

इदानीं य एते मध्यमा आनीता तेषां देशनियमार्थमार्ययाह—

लङ्कासमयाम्योत्तररेखायां भास्करोदये मध्याः ।

देशान्तरोनयुक्ता रेखायाः प्रागपरदेशेषु ॥३५॥

वा. भा.—लंकाउत्तरेण मेरुयावत् उज्जयिन्यादिदेशानां मध्येन या याम्योत्तररेखा सा लंकासमयाम्योत्तररेखा तत्र यो भास्करोदयकालः तत्रैव ते पूर्वानीता ग्रहा मध्याः । न तु पारे शेषदेशेष्वित्यर्थः किन्तु विषुवतीति वक्तव्यम् । यस्माच्चरदलवशात् अन्यत्र-कःलेऽर्कोदयरेखास्थदेशेष्वपि भिद्यते विषुवद्विषे, पुनः तुल्योऽर्कोदयो रेखावा-सिनामेतत्सर्वं गोले प्रदर्शयेत् । परिशेषदेशेषु विषुवद्विषे यथा मध्यमाः पूर्वानीताः स्वोदयिका भवन्ति । देशान्तरफलेन यथासंख्यमूनयुक्ताः संतः प्रागपरदेशेषु मध्या स्वोदये विषुवद्विने भवन्ति । यस्माद्रेखातः पूर्वेण यो द्रष्टा स रेखास्थद्रष्टुः सकाशात्पूर्वमेव रविमुदयन्तं पश्यति । अतो ग्रहफलं तत्र विशोध्यते । नागतदर्शना-त्पश्चात्तु दीयते वैपरीत्वादुपपन्नमेतत् । प्रवृत्तत्वाद्भूमेः एतत्सर्वं गोले प्रदर्शयेत् । वारप्रवृत्तिरपि याऽर्कोदये पूर्वमभिहिता सापि लंकासमयाम्योत्तरे रेखायां, नान्यत्र तावता च कालेनान्यदेशेषु विषुवद्विने भवति ।

वि. भा.—लङ्कासमयाम्योत्तररेखायां (लङ्कायाम्योत्तररेखायां) स्थितानां मानवानां भास्करोदये (मध्यमार्कोदयकाले) मध्याः (ग्रहर्गणसाधिता) मध्यमाः ग्रहा भवन्ति । रेखायाः प्रागपरदेशेषु (रेखातः पूर्वपश्चिमदेशेषु) गणितागतग्रहा देशान्तरोनयुक्ताः (देशान्तरफलेनोनयुताः) तदा स्वनिरक्षोदय-कालिका भवन्तीति ॥३५॥

अत्रोपपत्तिः

एतेनाऽचार्येणो- (ब्रह्मगुप्तेन) दयान्तरं न स्वीक्रियते तदात्वहर्गणेन (मध्यमसावनदिनसमूहेन) साधिता ग्रहा वस्तुतोऽहर्गणान्तेऽर्थमध्यमसावनान्ते समागच्छन्तोऽपि लङ्कायाम्योत्तररेखायां समागच्छन्ति, रेखातः पूर्वदेशे पूर्वमेव ग्रहदर्शनं भवति तेन रेखादेशीयग्रहादिद्विदेशीयग्रहस्याल्पत्वाद्देशान्तरफलेन स्पष्टभूपरि-धिना ग्रहगतिस्तदा देशान्तरयोजनैः किमित्यनुपातेन समागतदेशान्तरयोजनः-

अब ग्रहर्गण से साधित ग्रह कहां आते हैं सो कहते हैं

हि. भा.—लङ्कायाम्योत्तररेखा में स्थित मनुष्यों के मध्यमरव्युदय काल में ग्रहर्गण द्वारा साधित मध्यम ग्रह होते हैं, रेखा से पूर्व और पश्चिम देशों में क्रम से गणितागतग्रह में देशान्तर फल को घटाने और जोड़ने से अपने निरक्षोदयकालिक ग्रह होते हैं ॥३५॥

उपपत्ति

ग्रहर्गण मध्यम सावन दिनों का समूह है इसलिए ग्रहर्गण से साधित मध्यमग्रह ग्रहर्गणान्त बिन्दुक होते हैं, वह बिन्दु (मध्यम सावनान्त बिन्दु) क्रान्तिवृत्तस्थ मध्यमार्कोपरिगत ध्रुव प्रोतवृत्त नाडीवृत्त के सम्पात बिन्दु (स्पष्ट सावनान्त बिन्दु) से पदवश से ऊपर और नीचा होता है दोनों बिन्दुओं (मध्यमसावनान्त बिन्दु और स्पष्ट सावनान्तबिन्दु) के अन्तर को भास्कराचार्य उदयान्तर कहते हैं परन्तु ब्रह्मगुप्त उदयान्तर नहीं स्वीकार किये हैं इसलिए इनके मत से ग्रहर्गण द्वारा सिद्ध ग्रह लङ्कायाम्योत्तर रेखा में जो रहते हैं उनके मध्यमरव्युदय काल में होते हैं, रेखा से पूर्व देश में पहले ही ग्रह दर्शन होता है इसलिए रेखादेशीय ग्रह से अभीष्ट देशीय ग्रह के अल्पत्व के कारण देशान्तर फल को रेखादेशीय ग्रह में हीन करने से अभीष्ट देशीय ग्रह होते हैं। रेखा से पश्चिम देश में पीछे ग्रह दर्शन होता है इसलिए वहां रेखा देशीय ग्रह से अभीष्ट देशीय ग्रह के अधिकत्व के कारण रेखा देशीय ग्रह में देशान्तर फल को जोड़ने से अभीष्ट ग्रह होते हैं, इति ॥३५॥

अब वारादि को कहते हैं

हि. भा.—उज्जयिनी की दक्षिणोत्तर रेखा (रेखा) से पूर्वदेश में सूर्योदय के बाद
देशान्तर घटी करके दिनवारादि वारप्रवृत्ति होती है, रेखा से पश्चिम देश में देशान्तर घटी
करके सूर्योदय से पहले दिनवारादि होती है ॥३६॥

उपपत्तिः

लङ्कोदय काल में वारादि होती है. इस परिभाषा से रेखा से पूर्वदेश में सूर्योदय के
बाद देशान्तर घटी करके वारप्रवृत्ति होती है, रेखा से पश्चिम देश में सूर्योदय से
पहले उतने (देशान्तर घटी) ही काल पश्चात् प्रवृत्ति होती है । सिद्धान्त-
शिरोमणि में भास्कराचार्य भी “अर्कोदयाधूर्ध्वमधश्च ताभिः प्राच्यां प्रतीच्यां दिनप-

प्रवृत्तिः” इससे इसी ब्रह्मगुप्तोक्त बात को कहते हैं। वारप्रवृत्ति कब से होती है, इस विषय में बहुत आचार्यों के भिन्न-भिन्न बहुत मत हैं। जैसे आर्यभट्ट, सिद्धाचार्य आदि आचार्य ग्रहोदित रवि बिम्ब से दिनारम्भकाल को कहते हैं। अन्य आचार्य दिनार्ध से दिनारम्भ कहते हैं। लाटदेव आदि आचार्य रवि के अर्धस्तिकाल से उसको कहते हैं। यवन राजा रात्रि में दश मुहूर्त करके उसको कहते हैं, लाटाचार्य अपने सिद्धान्त ग्रन्थ में अर्धरात्रि से उसको कहते हैं। पञ्चसिद्धान्तिका में बराहमिहिराचार्य संस्कृतोपपत्ति में लिखित ‘दिनवारप्रवृत्तिर्न समा सर्वत्र कारणे कथिता’ इत्यादि पद्यों से इन्हीं विषयों को कहते हैं। सिद्धान्तशेखर में श्रीपति ने उपर्युक्त आर्यभटादि आचार्यों के मत का खण्डन किया है और ब्रह्मगुप्त कथित बात को स्वीकार किया है। जैसे—

सृष्टेर्मुखे ध्वान्तमये हि विश्वे ग्रहेषु सृष्टेर्ध्वनपूर्वकेषु ।
दिनप्रवृत्तिस्तदधीश्वरस्य वारस्य तस्मादुदयात्प्रवृत्तिः ॥

सृष्ट्यादि से पहले विश्व अन्धकारमय था जो संस्कृतोपपत्ति में लिखित भगवान् मनु ‘आसीदिदं तमोभूतमप्रज्ञातमलक्षणम्’ इत्यादि के इस वचन से विदित होता है, ऐसे समय में वारप्रवृत्ति के विचार सम्भव नहीं हैं क्योंकि उस समय में वारेश्वरग्रहों का अभाव रहता है। इसी कारण से रात्रि में वारप्रवृत्ति कहने वालों के मत ठीक नहीं कहे जा सकते हैं। मध्याह्न काल और अस्तमय काल से आरम्भ कर वारप्रवृत्ति कहना भी ठीक नहीं है, क्योंकि इस बात को स्वीकार करने से उतने काल तक दिन मानना पड़ेगा जो कि असङ्गत है। इसलिए रव्युदय काल से वारप्रवृत्ति मानने वाले आचार्य का मत ही ठीक है। इस मत में भी देश भेद से वारप्रवृत्ति में भेद होता है, जैसे—

संस्कृतोपपत्ति में लिखित ‘वारप्रवृत्तिं मुनयो वदन्ति सूर्योदयाद्रावणराजधान्याम्’ इत्यादि पद्य से विदित होता है, इसी को संस्कृतोपपत्ति में लिखित ‘लङ्कोदग्याम्यसूत्रा-त्प्रथममपरतः पूर्वदेशे च पश्चात्’— इत्यादि पद्य द्वारा स्पष्ट किया है इति ॥३६॥

इदानीं तदर्थं देशान्तरकर्मणा त्रयेण प्रदर्शयति

अत्रोपपत्तिः

यदि व्यासनानम् = १५८१ तदा व्यासवर्गद्विशगुणात्पदं भूपरिधिर्भ-
वेदिति सूर्यसिद्धान्तोक्त्या भूपरिधिमान ५००० मागच्छति ब्रह्मगुप्तमते ।

ध्रु-ख-ल-नि ध्रु = स्वयाम्योत्तरवृत्तम् ।

ध्रु, ध्रु ध्रुवौ, ख = स्वखस्वस्तिकम्, नि =
स्वनिरक्षस्वस्तिकम् । ध्रु-रे ध्रु = लङ्का-
याम्योत्तरवृत्ते रे कोऽपि रेखादेशः । नि-स-
नि' = नाडीवृत्तम् । रे-ल = नाडीवृत्तसमा-
नान्तरं लघुवृत्तम् । ल-नि = तद्रेखादेशा-
क्षांश सम्बन्धीनि योजनानि । यदि भग-
णांशैर्भूपरिधियोजनानि लभ्यन्ते तदा
स्वाक्षांशैः किमित्यनुपातेन स्वदेशाक्षांश-
योजनानि = $\frac{\text{भूप} \times \text{अक्षांश}}{३६०}$, एवमेव यदि-

भगणांशैर्भूपरिधियोजनानि लभ्यन्ते तदा रेखादेशाक्षांशैः किमित्यनुपातेन

रेखादेशाक्षांशयोजनानि = $\frac{\text{भूप} \times \text{रेखाक्षांश}}{३६०}$, रे-ख = रेखास्वदेशयोरन्तरयोजनानि ।

अत्राचार्येण रे-ल-ख त्रिभुजं सरलजात्यं स्वीकृतम् । तत्र रे-ल पूर्वापरान्तरं देशान्तर-योजनतुल्यम् । एतदानयनं क्रियते

$$\sqrt{\text{रेख}^2 - \text{लख}^2} = \sqrt{\text{रेख}^2 - \left\{ \frac{\text{भूप}}{३६०} (\text{स्वाक्षांश} - \text{रेखाक्षांश}) \right\}^2} = \text{रे-ल},$$

ततोऽनुपातो यदि स्फुटपरिधिना ग्रहगतिर्लभ्यते तदा देशान्तरयोजनैः किमित्यनुपातेन यत्कलात्मकं फलमागच्छति तद्रेखातः पूर्वदेशे पश्चिमदेशे च मध्यग्रहे स्फुटग्रहे वा क्रमशो हीनं घनं कार्यं तदा स्वदेशीयग्रहो भवति । एवं यदि स्पष्टभूपरियोजनैः षष्टिषटिका लभ्यन्ते तदा देशान्तरयोजनैः किमित्यनुपातेन यद् घट्यात्मकं फलमागच्छति तत्पूर्वपश्चिमदेशवशेन ग्रहवृत्तिथावृणधनं कार्यमिति,

ब्रह्मगुप्तेनात्र स्फुटभूपरिधेश्चर्चा न क्रियते, मध्यमभूपरिधिसम्बन्धेनैव देशान्तरघट्यानयनं कृतमतो न समीचीनमिति विवेचनीयं विज्ञरिति ॥३७-३८-३९॥

अत्र देशान्तर कहते हैं

हि. अ. — भूपरिधि ५००० पांच हजार है, इसको स्वदेश और रेखादेश के अक्षांशान्तर से गुणा कर अगणांश (३६०) से भाग देने से जो फल हो उसके वर्ग को देशान्तर (रेखादेश और स्वदेश के योजनात्मक अन्तर) वर्ग में घटाकर जो शेष रहे उसके मूल से ग्रहगति को गुणकर भूपरिधि (स्पष्टभूपरिधि) से भाग देने से जो कलात्मक फल हो उसको उज्जयिनीयाम्योत्तररेखा से पूर्वदेश में मध्यमग्रह में या स्फुटग्रह में ऋण करना, पश्चिमदेश में घन करना चाहिये, पद याने मूल (देशान्तर योजन) को साठ से गुणा कर भूपरिधि (स्पष्टभूपरिधि) से भाग देने से जो घट्यात्मक फल हो उसको पूर्व और पश्चिम देश में ग्रहवृत्ति तिथि में (तिथिमुक्त घटी) संस्कार करना चाहिये ॥३७-३८-३९॥

उपपत्ति

यदि व्यासमान = १५८१ मानते हैं तब 'व्यासवर्गाद्गुणात्पदं भूपरिधिर्भवेत्' इस सूर्यसिद्धान्तोक्त प्रकार से भूपरिधिमान = ५००० आता है, यही ब्रह्मगुप्तमत में भूपरिधिमान है । संस्कृतोपपत्ति में जो क्षेत्र लिखा हुआ है, वही यहां देखना चाहिये ।

धु-ख-ल-ध्रु = स्वयाम्योत्तरवृत्त है, ध्रु, ध्रु. दोनों ध्रुव हैं । ख = स्वस्वस्वस्तिक है, नि = स्वनिरक्ष खस्वस्तिक है, ध्रु-रे ध्रु. लंकायाम्योत्तरवृत्त में रे कोई रेखादेश है, नि-स-नि = नाडीवृत्त है, रे-ल = नाडीवृत्त के समानान्तर लघुवृत्त है, ल-नि = रेखादेशाक्षांश-

सम्बन्धियोजन है, अब अनुपात करते हैं यदि भगणांश में भूपरिधियोजन पाते हैं तो

स्वाक्षांश में क्या इस अनुपात से स्वदेशाक्षांशयोजनमान $= \frac{\text{भूप} \times \text{अक्षांश}}{३६०}$, इसी तरह

भगणांश में यदि भूपरियोजन पाते हैं तो रेखादेशाक्षांश में क्या इस अनुपात से रेखादेशाक्षांशयोजन $= \frac{\text{भूप} \times \text{रेखाक्षांश}}{३६०}$, रे-ख=रेखादेश और स्वदेश के अन्तर योजन

हां आचार्य ने रे-ल-ख त्रिभुज को सरलजात्य मान लिया है, रे ल पूर्वपरान्तर=देशान्तर-योजन इसका आनयन करते हैं

$$\sqrt{\text{रेख}^2 - \text{लख}^2} = \sqrt{\text{रेख}^2 - \left\{ \frac{\text{भूप}}{३६०} (\text{स्वाक्षांश} - \text{रेखाक्षांश}) \right\}^2} = \text{रेल, अब}$$

अनुपात करते हैं, यदि स्फुटपरिधि में ग्रहगति कला पाते हैं तो देशान्तरयोजन में क्या इस अनुपात से जो कलात्मक फल आता है उसको रेखा से पूर्वदेश में और पश्चिमदेश में मध्यमग्रह में या स्फुटग्रह में क्रम से ऋण और धन करने से स्वदेशीय ग्रह होते हैं। इसी तरह यदि स्फुट भूपरियोजन में साठ घटी पाते हैं तो देशान्तरयोजन में क्या इस अनुपात से जो घट्यात्मक फल आता है उसको पूर्व और पश्चिम देशवश से ग्रह की तरह तिथि (तिथि भुक्तघटी) में ऋण और धन करना चाहिये, यहां आचार्य (ब्रह्मगुप्त) स्फुट-भूपरिधि की चर्चा नहीं करते हैं, मध्यमभूपरिधि के सम्बन्ध ही से देशान्तर घट्यादि साधन करते हैं इसलिये यह ठीक नहीं है, इस विषय को विज्ञ लोग सोचें इति ॥ ३७-३८-३९ ॥

अत्र अधिशेषे—वर्षान्तक्षयघटी=शुद्धिरितिपरिभाषितमत उपपन्नमाचार्योक्तमिति ॥ ४१ ॥

अब वर्षादि में अधिमासानयन करते हैं

हि. भ०.—पूर्वसाधित दिनादि—क्षयाहादि और दशगुणित गतवर्षों के योग को तीस से भाग देने से अधिमास होता है, दिनांश (अवमदिनांश) से जो शेष रहता है

वह दिनादि शुद्धि होती है अर्थात् अधिशेष तिथि में क्षयशेष को घटाने से शेष शुद्धि संज्ञक होता है ॥ ४१ ॥

उपपत्ति

एकवर्ष में सावन दिन = ३६५।१५।३०।२२।३० = ३६५ + १ वर्षसंदिनादि
एकवर्ष में क्षयाहादि = ५।४८।२२। ७।३० = ५ + १ वर्षसंक्षयघट्यादि

दोनों के योग करने से

एकवर्ष में चान्द्रदि = ३७१।३।५२।३० = ३७० + १ वर्षसंदिनादि + १ वर्ष-
संक्षयाहादि

एकवर्ष में सौरदिन = ३६० = ३६०

दोनों के अन्तर करने से

एकवर्ष में अधिदिन = ११।३।५२।३० = १० + १ वर्षसंदिनादि
+ १ वर्षसंक्षयाहादि

∴ अनुपात करने से

$$\begin{aligned} \text{गताधिसास} &= \frac{१ \text{ वर्षसंअधिदिन} \times \text{गतवर्ष}}{१ \text{ वर्ष } ३०} \\ &= \frac{(१० + १ \text{ वर्ष संदिनादि} + १ \text{ वर्षसंक्षयाहादि}) \times \text{गव}}{३०} \\ &= \frac{१० \text{ गव} + १ \text{ वर्ष संदिनादि} \times \text{गव} + १ \text{ वर्षसंक्षयाहादि} \times \text{गव}}{३०} \\ &= \frac{१० \text{ गव} + \text{गतवर्ष संदिनादि} + \text{गतवर्षसंक्षयाहादि}}{३०} \end{aligned}$$

यहां अधिशेष—वर्षान्तक्षयशेष = शुद्धिसंज्ञक, इससे आचार्योंक्त उपपन्न हुआ ॥ ४१ ॥

अब वर्षशानयन और लघ्वहर्गणानयन कहते हैं

हि. भा.—कल्पादि से जो गतवर्ष है उसका और गतवर्षसम्बन्धि दिनाद्यों का योग सूर्यादि वर्षपति होते हैं । कल्पगतवर्ष और कल्पग्रहभरण के घात (गुणनफल) को कल्पवर्ष से भाग देने से जो फल होता है वह सूर्यभरणान्त में (रविवर्षान्त में) मध्यमग्रह होते हैं । चैत्रशुक्लप्रतिपदादि से वर्तमान मास की इष्टतिथि पर्यन्त जो तिथियां हैं उनमें शुद्धि को घटा देने से जो हो उसको दो स्थान में स्थापित करना, एक स्थान में उसे ग्यारह ११ से गुण देना, वर्षादिकक्षयशेष को ६९२ इनसे गुणा कर अपने हर ६६०० से भाग देकर जो फल हो उसे ग्यारह गुणित शुद्धि रहित इष्टतिथि में जोड़ देना ७०३ इनसे भाग देने से जो लब्धि अवम हो उसको पूर्वस्थापित (द्वितीय स्थान स्थित शुद्धि रहित इष्टतिथि) में घटाने से रविमेषादि (जिस काल में रविमेष में जाते हैं उस काल) से ग्रहर्गण (लघ्वहर्गण) होता है, इसको सात से भाग देने से जो शेष रहता है वह अब्दपत्यादि (वर्षपत्यादि) होते हैं ॥४२-४३॥

उपपत्ति

एक वर्ष में सावनदिनादि = ३६५।१५।३०।२२।३०, इष्टवर्षान्त में सावनदिनादि = गव (३६५।१५।३०।२२।३०) = गव × ३६५ + गव (१५।३०।२२।३०) = गव ३६५ + गतवर्षसंदिनादि = कल्पादि से इष्टवर्षान्त में सावनाहर्गण इसमें दिनादिवोधक द्वितीय खण्ड ही है, आनीत सावनाहर्गण में सात से भाग देने जो शेष रहता है वह रव्यादि वर्षपति होते हैं कल्पादि में रविवार या इसलिये रवि ही से गणना करते हैं, अब रविभरणान्त (रविवर्षान्त) में ग्रहानयन के लिये अनुपात करते हैं यदि कल्पवर्ष में कल्पग्रह भरण पाते हैं तो गतवर्ष में क्या इस अनुपात से रविवर्षान्त में मध्यमग्रह आते हैं, इससे आचार्योंक उपपन्न हुआ ॥४१॥

लघ्वहर्गण साधन के लिये वर्षादि से गततिथि = इष्टतिथि — अश्विसेति; तथा स्वल्पान्तर से ७०३ चान्द्र दिनों में ग्यारह ११ अवम होते हैं यह मानकर अनुपात 'यदि ७०३ चान्द्रदिनों में ग्यारह ११ अवम पाते हैं तो वर्षादि से गततिथि में क्या' इससे जो फल आता है उसमें वर्षादिकक्षय शेष जोड़ने से पूरे अवम होते हैं, उसका स्वरूप यह है जैसे—

$$\frac{११ \text{ (इष्टति — अश्विसेति)}}{७०३} + \frac{\text{वर्षादिकक्षय}}{६६००}$$

$$\begin{aligned}
 &= \frac{११ \text{ (इष्टति—अधिशेति) } + \frac{७०३ \text{ वक्षशे}}{६६००}}{७०३} \\
 &= \frac{११ \text{ (इष्टति—अधिशेति) } + \frac{११ \text{ वक्षशे}}{६६००} + \frac{६६२ \text{ वक्षशे}}{६६००}}{७०३} \\
 &= \frac{११ \left\{ \text{इष्टति—} \left(\text{अधिशेति—} \frac{\text{वक्षशे}}{६६००} \right) \right\} + \frac{६६२ \text{ वक्षशे}}{६६००}}{७०३} \\
 &= \frac{११ \text{ (इष्टति—शुद्धि) } + \frac{६६२ \text{ वक्षशे}}{६६००}}{७०३} =
 \end{aligned}$$

अवम

∴ लघ्वहर्गण = (इष्टति—शुद्धि)—अवम इससे आचार्योक्त उपपन्न हुआ ॥४३-४४॥

लघ्वहर्गण कब सावयव और निरवयव होता है इसके लिये विचार करते हैं । जब अवमशेष का अभाव होगा तब सूर्योदय—अमान्त और वर्षान्त के एक ही स्थान में रहने के कारण चान्द्राहर्गण-सौराहर्गण और सावनाहर्गण निरवयव होंगे यह सिद्ध हुआ । कल्प में निरग्रलक्षण कितने होते हैं इसके लिये विचार—जब निरग्रलक्षण हैं तब अहर्गणों- (सौराहर्गण-चान्द्राहर्गण और सावनाहर्गण) के महत्तमापवर्तनाङ्क निकालना उससे पूर्वोक्त अहर्गणों को अपवर्तित करने से जो लब्धियां हों तत्तुल्य वर्षों में फिर फिर वे अहर्गण निरवयव होंगे । अपवर्तित सौराहर्गण मान कितने वर्षों में वर्षान्त में होता है उसके लिये विचार—सौराहर्गण को महत्तमापवर्तनाङ्क से अपवर्तित करने से जितने दिने आवें उनको तीन सौ साठ ३६० से भाग देने से जो शेष रहे उसको जिस अङ्क से गुणने से तीन सौ साठ ३६० हो उसी गुणक तुल्य वर्षों में अपवर्तित सौराहर्गण वर्षान्त में होगा यह सिद्ध हुआ । इसी तरह अपवर्तित चान्द्राहर्गण और सावनाहर्गण कितने वर्षों में वर्षान्त में होंगे इसका भी विचार करना । जैसे सौराहर्गण के साथ चान्द्राहर्गण और सावनाहर्गण का महत्तमापवर्तनाङ्क निकालना तब उस अपवर्तनाङ्क से चान्द्राहर्गण और सावनाहर्गण को अपवर्तित करना तब लब्ध तुल्य वर्षों में फिर वे दोनों वर्षान्त में होंगे । यह विषय वटेश्वर सिद्धान्त में भी मैंने लिखा है इति ॥४३-४४॥

इदानीमहर्गणग्रहानयनविवक्षुरादौ तावद्रविसितबुधानां कुजगुरुशनिशीघ्रो-
च्चानां चानयनायायिमाह ।

संकायां भवतीत्युपपन्नम् । अनयैव विपरीतवासनया चन्द्रे ज्ञाते अवमावशेषमा-
नयेत् यो मध्यमः इति ॥ ४६ ॥

वि. भा.—अवमावशेषं (खयशेषं) त्रिगुणं गुणसप्तशशिभिः (१७३ एभिः)
विभजेत्, लब्धांशैः पृथगर्को युतो रविगुणतिथ्यंशैः (द्वादशगुणिततिथ्यंशैः)
संयुतस्तदा चन्द्रो भवतीति ॥४६॥

उपपत्तिः

$$\text{अत्राचार्यमतेनावमशेषम्} = \frac{\text{अशे}}{७०३},$$

इदं सावनं, चान्द्रकरणेन—

$$\text{चान्द्रावमशेषम्} = \frac{\text{अशे} \times ७०३}{७०३ \times ६६२} = \frac{\text{अशे}}{६६२}$$

$$\text{द्वादशगुणमंशात्मकम्} = \frac{\text{अशे} \times १२}{६६२} = \frac{\text{अशे} \times ३}{१७३}$$

अथ चन्द्रार्कयोरन्तरभागा द्वादशभक्ता तिथिः स्यात्

∴ तिथ्यन्ते रविचन्द्रान्तरभागाः = १२ ति = चा-२.

∴ च = १२ ति + २ अत्रावमभागयोगेनौदयिकश्चन्द्रः = १२ ति + २ +

$\frac{३ \text{ अशे}}{१७३}$ उपपन्नमाचार्योक्तम् ।

अथ चन्द्रानयन कहते हैं

हि. भा.—अवमावशेष (क्षयशेष) को तीन से गुणाकर एक सौ तेहत्तर १७३ से भाग देने से जो लब्धांश होता है रवि में जोड़ना और बारह गुणित तिथ्यंश को जोड़ने से अंशात्मक चन्द्र होते हैं इति ॥४६॥

हिन्दी में अन्य ढंग से उपपत्ति

$$\text{अहर्गणान्त कालिक तिथि} = \text{गति} + \text{क्षयघटीसंचान्द्र}, \frac{\text{अंशात्मक चं}-\text{अंशात्मक र}}{१२} = \text{तिथि}$$

इसलिए अंशात्मक चं = अंशात्मक र + १२ तिथि, अतः अहर्गणान्तकालिक चं = अंशात्मक र

$$+ १२ (\text{गति} + \text{क्षयसंचां}) = \text{अंशात्मक र} + १२ \text{ गति} + १२ \text{ क्षयसंचां} \frac{१ \text{ क्षय} \times ६४ \text{ चां}}{६४ \text{ चान्द्र}}$$

$$= \text{गसादि} + \frac{\text{क्षये}}{६४} \therefore \frac{\text{क्षयशे}}{६४} = \frac{\text{क्षय}}{६०} \text{ इसलिए अनुपात से क्षयघटीसंचांदि}$$

$$= \frac{६४ \text{ चां} \times \text{क्षये}}{६३ \text{ सावन} \times ६४} = \frac{\text{क्षये}}{६३} \therefore १२ \text{ क्षयसंचां} = \frac{१२ \text{ क्षये}}{६३} \text{ एतत्सम्बन्धी कलात्मक फल}$$

$$= \frac{१२ \times ६० \times \text{क्षये}}{६३} = \frac{२० \times १२ \times \text{क्षये}}{२१} = \frac{२० \times ४ \text{ क्षये}}{७} = \frac{८० \text{ क्षये}}{७} \text{ इसको अंशात्मक करने}$$

से $\frac{८० \text{ क्षशे}}{६० \times ७} = \frac{८० \text{ क्षशे} \times ३}{६० \times ७ \times ३} =$ परन्तु आचार्य कथित क्षयशेष को गया रहसे भाग देने से भास्कर-

$$\text{कथित क्षयशे} = \frac{\text{क्षयशे}}{११} \therefore \frac{८० \text{ क्षशे} \times ३}{६० \times ११ \times ७ \times ३} = \frac{\text{क्षशे} \times ३}{७ \times ११ \times ६० \times ३} = \frac{\text{क्षशे} \times ३}{१३८६}$$

$$= \frac{\text{क्षशे} \times ३}{६६३} = \frac{\text{क्षशे} \times ३}{१७३} = १२ \text{ क्षयषसंचां भतः अहर्गणान्त कालिक अंशात्मक चन्द्र} =$$

अंशात्मकरवि + १२ गति + $\frac{\text{क्षशे} \times ३}{१७३}$ इससे आचार्योक्त उपपन्न हुआ इति ॥४६॥

इदानीं वर्षान्तिकादहर्गणात् भौमादिग्रहमन्दफलानयनार्थमार्याचतुष्टयमाह

$$\text{अथ } ०'' १२२''' १५१'''' = ०.१२२ + \frac{५१}{६०} = ०.१२२ + \frac{१७}{२०} = ०.१ \frac{४४० + १७}{२०} = ०.$$

$$\frac{४५७}{२०} = ० + \frac{४५७}{६० \times २०} = \frac{४५७}{१२००} = \frac{४५७ \times २}{१२०० \times २} = \frac{२}{१२०० \times २} = \frac{२''}{४५७} \quad \text{कला-}$$

$$\text{त्मक करणेन } \frac{२}{५ \times ६०} = \frac{२}{३००} = \frac{२}{३१५} \quad \text{स्वल्पा ततः शनिगतिः } २' + \frac{२'}{३१५} \quad \text{ततः}$$

$$\text{कलात्मकशनिः} = २ \text{ अहर्गण} + \frac{२ \text{ अहर्गण}}{३१५} \quad \text{एतेनाचार्योक्तमुपपद्यते । यदि चै}$$

$$\frac{२}{५} \text{ तत्कलात्मकं न क्रियते तदा } २' + \frac{२''}{५} = \text{शनिगतिः, ततः शनिः} = २ \text{ अहर्गण}$$

+ $\frac{२ \text{ अहर्गण}}{५}$ एतेन 'द्विघ्नो दिनीघः पृथगक्षभक्तो लिप्ता विलिप्ता ध्रुवकेस्वमा-
किरिति' भास्करोक्तमुपपद्यत इति ।

एवमेवैकदिनसम्बन्धिनीमाचार्योक्तां कलादिकां $६'१४०''१५३'''१५६''''$
चन्द्रोच्चगतिं संगृह्य पूर्वोक्तवत्क्रियाकरणेन चन्द्रोच्चमंशाद्यम् + $\frac{\text{अहर्गण}}{६} = \frac{\text{अहर्गण}}{४००४}$
एतावताऽऽचार्योक्तं सर्वमुपपद्यत इति ॥४६॥

अब शनि और चन्द्रोच्च के आनयन को कहते हैं

हि. मा.—श्लोकोक्ति से कलात्मकशनि = २ अहर्गण + $\frac{२ \text{ अहर्गण}}{३१५}$, अंशादि-
चन्द्रोच्च = $\frac{\text{अहर्गण}}{६} + \frac{\text{अहर्गण}}{४००४}$ ॥४६॥

उपपत्ति

एकदिन में शनि की कलादिक गति = $२'१०''१२२'''१५१''''$ भास्कराचार्योक्त भी
इतनी ही है, $०''१२२'''१५१'''' = ०.१२२ + \frac{५१}{६०} = ०.१२२ + \frac{१७}{२०} = ०.१ \frac{४४० + १७}{२०}$
 $= ०.१ \frac{४५७}{२०} = ० + \frac{४५७}{६० \times २०} = \frac{४५७}{१२००} = \frac{४५७ \times २}{१२०० \times २} = \frac{२}{१२०० \times २}$
 $\frac{४५७}{४५७}$
 $= \frac{२''}{५}$ कलात्मक करने से $\frac{२}{५ \times ६०} = \frac{२}{३००} = \frac{२}{३१५}$ स्वल्पान्तर से \therefore शनिगति
 $= २' + \frac{२'}{३१५}$ अतः कलात्मकशनि = २ अहर्गण + $\frac{२ \text{ अहर्गण}}{३१५}$ इससे आचार्योक्त
उपपन्न हुआ । यदि $\frac{२''}{५}$ इसको कलात्मक नहीं करते हैं तो शनिगति = $२' + \frac{२''}{५}$ अतः
शनि = अहर्गण $\left(२' + \frac{२''}{५} \right) = २ \text{ अहर्गण} + \frac{२ \text{ अहर्गण}}{५}$ इससे 'द्विघ्नो दिनीघः पृथगक्ष-
भक्तो लिप्ता विलिप्ता इत्यादि' भास्करोक्त उपपन्न होता है ॥ एवं एकदिनसम्बन्धिनी
आचार्योक्त कलादिक चन्द्रोच्चगति $६'१४०''१५३'''१५६''''$ से पूर्वोक्तवत् क्रिया करने से

अंशादि चन्द्रोच्च = $\frac{\text{अहर्गण}}{६} = \frac{\text{अहर्गण}}{४००४}$ होता है, इससे आचार्योक्त सब उपपन्न हुआ ॥४६॥

= इष्टवर्षान्ते भगणादिग्रह । अत्र प्रथमखण्डे यद्भगणाशेषमानं तस्य क्षेपसंज्ञा कृताऽऽचार्यैरेत्येतावताऽऽचार्योक्तमुपपन्नम् सिद्धान्तशेखरे श्रोपांतना प्रथमखण्डजनितफलस्यैव ग्रहध्रुवसंज्ञा कृता, यथा तदुक्तं, यातवर्षखगपर्ययाहते कल्पवर्षविहृते ग्रहध्रुवाः । ते भवन्ति रविमण्डलान्तिका इति ॥ ५२-५३-५४-५५-५६-५७ ॥

अब कलिगतवर्ष ही से शुद्धि आदि के ग्रहानयन के लिए विशेष बात और रविवर्षान्तकालिक ग्रहानयन के लिये प्रकारान्तर को कहते हैं

हि. भा.—पूर्ववत् कलिगत शुद्धि साधन करना अर्थात् पहले कल्पगत वर्षों से जिस तरह शुद्धि लायी गई है उसी तरह कलिगत वर्षों से साधन करना, किन्तु कलि के आदि में शुक्रवार था इसलिये वर्षपति की गणना शुक्रवार से होती है । श्लोकों में जो पठिताङ्क हैं वे मङ्गल, वृहस्पति, शनैश्चर इन ग्रहों के, रवि और चन्द्र के मन्दोच्चों के, बुध और शुक्र के शीघ्रोच्चों के तथा चन्द्रपात के क्षेपसंज्ञक हैं, कलिगत वर्षों के और ग्रह भगणों के घात में पाठ्यठित अपने-अपने क्षेप जोड़कर कल्पवर्ष से भाग देने से जो भगणादि लब्धिप्रमाण आता है वे रविमण्डलान्तिक (रविवर्षान्तकालिक) मध्यम ग्रह होते हैं उनमें मेवादि द्युगण फल (लघ्वहर्गणोत्पन्नग्रह) को जोड़ने से अभीष्ट वर्षान्त में मध्यम ग्रह होते हैं इति ॥ ५२, ५३, ५४, ५५, ५६, ५७ ॥

उपपत्ति

रविवर्षान्त में ग्रहानयन के लिये अनुपात करते हैं, यदि कल्पवर्ष में कल्प ग्रह भगण पाते हैं तो कल्पगतवर्ष में क्या इस अनुपात से अभीष्ट वर्षान्त में भगणादि मध्यमग्रह आते हैं ।

कल्पग्रह × कल्पगतवर्ष
कल्पवर्ष

= अभीष्टवर्षान्त में भगणादिग्रह, यहाँ आचार्य ने कल्पगतवर्ष

के दो खण्ड 'कल्यादि से कल्यादि तक प्रथम खण्ड, और कल्यादि से इष्टवर्षान्त तक द्वितीय खण्ड' किये हैं, तब इनसे कल्पगतवर्ष के उत्थापन करने से $\frac{\text{कल्पग्रह} \times \text{कल्यादि से कल्यादितकवर्ष}}{\text{कल्पवर्ष}} + \frac{\text{कल्पग्रह} \times \text{कलिगतवर्ष}}{\text{कल्पवर्ष}} = \text{अभीष्टवर्षान्त में भगणादिग्रह}$

यहाँ प्रथम खण्ड में जो भगण शेष रहता है उसी का नाम आचार्य ने क्षेप रक्खा है । इससे आचार्योक्त उपपन्न हुआ । पूर्वोक्त प्रथमखण्डगतग्रहों को सिद्धान्तशेखर में श्रीपति 'यातवर्ष खगपर्ययाहते कल्पवर्षविहृते ग्रहध्रुवाः । ते भवन्ति रविमण्डलान्तिकाः' इससे ग्रह ध्रुवा कहते हैं इति ॥ ५२-५३-५४-५५-५६-५७ ॥

अब रविवर्णान्त और चैत्रादि के मध्य में कितने सावनदिन हैं उनका साधन करते हैं

हि. भा.—अवमशेष रविवर्णान्त में जो क्षयशेष है उसको ६६२ इससे गुणाकर
अपने हर (६६००) से भाग देने से जो फल होता है, में पूर्वकथित शुद्धि और ग्यारह के
घात (गुणनफल) को घटा देने से सावनाहर्गण की शुद्धि होती है अर्थात् "हतास्त्रिस्त्रागैः
फलावमविहीना इत्यादि" आचार्योक्त प्रकार से चैत्रादि में सावनाहर्गण की सिद्धि होती
है । यदि अवमशेष में शुद्धि और ग्यारह की घात न घटे तब रविवर्णान्त में कल्प से जितने
अवम हों उनमें एक घटाकर अवमशेष में ७०३ जोड़कर जो हो उसमें उस घात (गुणनफल)
को घटा देना चाहिये इति ॥ ५८ ॥

उपपत्ति

चैत्रादितिथि = ० तब विपरीत शोधन ने चैत्रादिगति—शुद्धि = ०—शुद्धि = —
शुद्धि, तब 'अवमांशेभ्यो यमनवरसगुणितेभ्य इत्यादि आचार्योक्त प्रकार से' अवमशेष-

$$\text{स्वरूप} = \frac{६६२ \text{ वक्षयशेष}}{६६००} - ११ \text{ शुद्धि, यदि } ११ \text{ शुद्धि} > \frac{६६२ \text{ वक्षयशेष}}{६६००} \text{ तब अवमशेष प्रमाण}$$

ऋणात्मक होता है, तब लब्धि = — इष्टक्षयशेष = — अवमशेष, धनात्मक के लिये एक
जोड़ने से

$$1 + \frac{\frac{६६२ \text{ वक्षयशेष}}{६६००} - ११ \text{ शुद्धि}}{७०३} = \frac{\frac{६६२ \text{ वक्षयशेष}}{६६००} - ११ \text{ शुद्धि} + ७०३}{७०३} = \text{चैत्रादि में}$$

अवमशेष, यदि चैत्र शुक्लादि रविवर्णान्त से पहले हो तब विलोमाहर्गण होता है, इसी को
लल्लाचार्य आदि आचार्य चैत्रादि में ऋणाहर्गण कहते हैं । सिद्धान्तशेखर में श्रीपति 'शुद्धि-
मेव पृथगीश्वराहतां शोधयेदवमशेषकान्निजात् इत्यादि' से ब्रह्मगुप्तोक्त प्रकार ही कहते हैं
इसको विवेचक लोग समझें इति ॥ ५८ ॥

अश्रोपपतिः

रविवर्षान्तामान्तयोर्मध्यवर्तित्यस्तिथयोऽधिशेषतिथयस्ततो वर्षान्तक्षयशेष-
घटिकाः शोध्याः शेषस्य शुद्धिसंज्ञा सैव वर्षान्तामान्तयोर्मध्ये सावनदिनसंख्या ।
रविवर्षान्तामान्तयोर्तरे सावनदिनानि = शुद्धिः कल्पादित इष्टसौरवर्षान्तं
यावत्सावनदिनानि = ३६५ गव + दिनादि, ततः कल्पादित इष्टसौरवर्षान्तं

यावत्सावनदि—शुद्धि=३६५ गव+दिनादि—शुद्धि=चैत्रादौ सावनदिनानि,
एतानि सप्तभिर्भक्तानि वर्तमानवारार्थं रूपयोजितानि तदा चैत्रसिताद्वारः=
गव+दिनादि—शुद्धि+१ एतावताऽऽचार्योक्तमुपपद्यते । सिद्धान्ततत्त्वविवेके
कमलाकरेण लघ्वहर्गणानयने वारगणनार्थं विशेषः प्रतिपादितोस्तीति ॥५६॥

अब चैत्रादि से अहर्गणानयन करके मध्यग्रहानयन को कहते हैं

हि. भा.—पूर्वसाधित दिनादि—कल्पगतवर्ष और रूप (एक) इन सबों के योग में शुद्धि को घटाकर जो हो उस पर से चैत्रसितादिवर्षपति साधन करना, अर्थात् दिनाद्य-कल्पगतवर्ष और रूप इन सबों के योग में शुद्धि को घटाकर जो शेष बचे उसको सात से भाग देने से चैत्रादि में रव्यादिवार होते हैं । चैत्रादि से जो अहर्गण होता है उसमें चैत्रादिवार से दिनवार समझना चाहिए, उससे जो ग्रह होते हैं उसमें शुद्धिदिनोत्पन्नग्रह को घटाने से सौरवर्षान्त से पूर्ववत् मध्यम ग्रह होते हैं ॥५६॥

उपपत्ति

सौरवर्षान्त और अमान्त के मध्य में जो तिथि है वह अधिशेष तिथि है, उसमें वर्षान्तक्षयशेष घटी को घटाने से जो शेष रहता है उसका नाम शुद्धि है, वही वर्षान्त और अमान्त के मध्य में सावनदिन है, रविदिवर्षान्त और अमान्त के मध्य में सावन दिन=शुद्धि, कल्पादि से इष्टसौरवर्षान्तपर्यन्त सावनदिन=३६५ गव+दिनादि,

अतः कल्पादि से इष्टसौरवर्षान्तपर्यन्तसावनदि-शुद्धि=३६५ गव+दिनादि—शुद्धि=चैत्रादि में सावनदिन इसको सात से भाग देना और वर्तमान वार के लिये रूप जोड़ देना तब चैत्रसितादि से वार होते हैं, चैत्रसितादि से वार=गव+दिनादि—शुद्धि+१ इससे आचार्योक्त उपपन्न हुआ । कमलाकर ने सिद्धान्ततत्त्वविवेक में लघ्वहर्गणानयन में वार गणना के लिये बहुत विशेष विचार किया है, कभी-कभी बिना रूप जोड़ने से भी चैत्रादि में वार होते हैं, वर्तमान वारज्ञानार्थं अहर्गण में सैक और निरेक किया जाता है जिसको भास्कराचार्य ने भी सिद्धान्तशिरोमणि में 'अभीष्ट वारार्थमहर्गणश्चेत्' इत्यादि से कहा है इति ॥५६॥

अब बीज कर्म कहते हैं

हि. भा.—कल्पगत वर्ष में बारह हजार (१२०००) से भाग देने से जो लब्धि होती है वह गत है, उसको हर १२००० में घटाने से जो शेष रहता है वह गम्य है, इन दोनों में जो अल्प हो उसे दो सौ से भाग देने से जो लब्धफल हो उसे तीन और पाँच से गुणने से जो कलात्मक फल हो उनको क्रम से रवि और चन्द्र में ऋण करना, चन्द्र में जो कलात्मक फल ऋण किया गया है वही वृहस्पति में भी ऋण करना चाहिये। उसी फल को दो से गुणाकर चन्द्रमन्दोच्च में ऋण कर देना चाहिये, उसी फल को पन्द्रह से गुणा कर जो हो उसे शुक्र के शीघ्रोच्च में ऋण करना। उसी फल को बावन ५२ से गुणाकर जो हो उसे बुधशीघ्रोच्च में ऋण करना चाहिये। उसी फल को दो, एक और चार से पृथक्-पृथक् गुणा करके जो हो उन्हें क्रम से पात, मङ्गल और शनि में ऋण करना चाहिये ॥ ६०-६१ ॥

उपपत्ति

‘इष्टग्रहभगणगुणात्’ इत्यादि ब्रह्मगुप्तोक्तप्रकार से या ‘द्युचरचक्रहतो दिनसंचयः’ इत्यादि भास्करोक्तप्रकार से साधित क्रान्तिवृत्तीय मध्यम ग्रह से स्फुट क्रिया करने से वास्तव स्फुट ग्रह नहीं आते हैं, लेकिन इस मध्यम ग्रह में बीजकर्म जनित फल को संस्कार करने से जो मध्यम ग्रह होते हैं उससे स्फुट क्रिया करने से वास्तव स्फुटग्रह आते हैं, यह बात प्रागमवादी लोग कहते हैं। वस्तुतः इसमें कुछ प्रामाणिकता नहीं है।

उपपत्ति से मानयन योग्य कितने दिनों में उपलब्ध भूत पदार्थ बीज शब्द से कहा जाता है उसका कर्म बीजकर्म कहलाता है, उन २ पदार्थों की सृष्ट्यादि से लेकर छः हजार वर्ष पर्यन्त वृद्धि होती है उससे आगे छः हजार वर्ष पर्यन्त ह्रास होता है इसमें आगम ही प्रमाण है, इसलिये सृष्ट्यादि से छः हजार वर्षान्त में परमवृद्धि होती है, बारह हजार वर्षान्त में परम ह्रास होता है यह निर्गलितार्थ हुआ; इस तरह प्रत्येक बारह हजार वर्ष में होता है, इसलिये इष्ट काल में जो गत सौर वर्ष हो उसे बारह हजार से भाग देने से जो शेष रहे उस पर से अनुपात द्वारा फल लेकर मध्यम ग्रह में संस्कार करने से स्फुट क्रिया करण योग्य मध्यम ग्रह होंगे, यदि शेष < ६००० वर्ष तब फल वृद्धयभिमुख होता है, यदि शेष > ६००० वर्ष तब फल ह्रासोन्मुख होता है। यदि शेष < ६००० वर्ष तब

शेष < १२०००—शेष=शेष^१ लेकिन दोनों शेषों के अनुपात से फल एक ही होता है इसलिये अङ्कलाघव के लिये यहां 'शे' इसी से अनुपात करना ठीक है। यदि शे > ६०००

वर्ष तब शे > १२०००—शेष=शेष^१ यहां भी दोनों शेषों से फल एककालीन ही होता है, यहां अङ्क लाघव के लिये शे इसी से अनुपात करना ठीक है, इसलिये अनुपात करते हैं

$$\frac{\text{परमोपचयफल} \times \text{शेष}}{६०००} = \frac{\frac{\text{परमोपचयफल}}{३०} \times \text{शेष}}{२००} = \text{फल यहां रवि आदि ग्रहों के और}$$

पातादियों के परम बीज फलों को तीस से भाग देने से क्रम से ३, ५, ५, १५, २, १, ५, २, ४ होते हैं, यहाँ अनुपातागत फलों को यदि रवि, चन्द्र, बृहस्पति, चन्द्रमन्दोच्चादि में श्रृणु करते हैं तब स्फुट क्रियाकरण योग्य मध्यम ग्रह होते हैं, इसमें आगम ही प्रमाण है।

इस तरह शे इससे भी उसी तरह अनुपात होता है क्योंकि बारह हजार वर्षान्त से विलोम क्रम से यह काल होता है वहाँ फल वृद्धि के तरफ होता है, क्योंकि बारह हजार वर्षान्त में फल का परमह्रास होता है, उस काल से विलोम क्रम से फल की सत्ता क्रम से अधिक ही होती है, इसलिये अनुपात से दोनों जगह फल की तुल्यता ही होती है, इसलिये

$$\frac{\text{परमवृफल} \times \text{शेष}^1}{६०००} = \text{फल} = \frac{\frac{\text{पवृफल}}{३०} \times \text{शेष}^1}{२००} \text{ इससे आगे पूर्ववत् होता है, यहां वर्षशब्द से}$$

सौरवर्ष ही ग्रहण करना चाहिये। भास्कराचार्य सिद्धान्तशिरोमणि में रवि, चन्द्र, बृहस्पति, शुक्रशीघ्रोच्च, चन्द्रमन्दोच्चों में अनुपातागत फलों को श्रृणु कहते हैं तथा मङ्गल बुध, चन्द्र, पात, शनि इनमें अनुपातागत फल को धन कहते हैं, ब्रह्मगुप्त सबों में अनुपातागत फलों को श्रृणु ही कहते हैं, सिद्धान्ततत्त्वविवेक में कमलाकर ने बीज कर्म संस्कार का खण्डन किया है। इनमें क्या ठीक है, इस विषय में प्रबल युक्ति नहीं मिलती है, इसलिये इस विषय में हम कुछ नहीं कह सकते ॥ ६०-६१॥

इदानीं चन्द्रमन्दोच्चपातयोरार्यभटोक्त्या दूषणमाह

गणितमेव शरणमिति ॥६२॥

अथ आर्यभटोक्त चन्द्रोच्च और चन्द्रपात के दोष को कहते हैं

हि. भा.—आर्यभट ने मेरी चन्द्रमन्दोच्चगति से चन्द्रमन्दोच्च को शीघ्रगति किया है
अर्थात् मेरी चन्द्रमन्दोच्च गति से अपनी (आर्यभटीय) चन्द्रमन्दोच्चगति को अधिक

किया है और मेरी चन्द्रपातगति से अपनी चन्द्रपातगति को अल्प किया है, इसलिये तिथ्यन्त और ग्रहणों में यदि मेरे मत के साथ आर्यभट मत का ऐक्य (एकता) हो तो उसको (मतैक्य को) घुणाक्षर समझना चाहिए अर्थात् काठ को घुण (कीड़ा विशेष) के खाने से कभी-कभी अक्षर का आकार बन जाता है तो उससे यह नहीं समझा जाता है कि घुण ने अपनी बुद्धि से अक्षर बनाया है, उसी तरह मतैक्य के सम्बन्ध में भी समझना चाहिये ।

कल्प में आर्यभटोक्त चन्द्रमन्दोच्चभगण = ४८८२१६०००, मेरे मत से कल्प में चन्द्रमन्दोच्चभगण = ४८८१०५८५८ < ४८८२१६००० तथा कल्प में आर्यभटोक्त चन्द्रपातभगण = २३२२२६०००, मेरे मत से कल्पचन्द्रपातभगण = २३२२१११६८ > २३२२२६००० इसलिये मेरी चन्द्रमन्दोच्चगति और पातगति से आर्यभटोक्त उनकी गति अधिक और अल्प होने के कारण आर्यभट का मत ठीक नहीं है यह ब्रह्मगुप्त कहते हैं, ब्रह्मगुप्त अपने मत को बिल्कुल ठीक समझ कर अपने मत से आर्यभट मत के पृथक् होने के कारण उसका खण्डन करते हैं, ब्रह्मगुप्त का कथन ठीक है या नहीं इसके लिये गणित ही शरण है इति ॥ ६२ ॥

इदानीं स्वकृताया मध्यगतेः प्रशंसार्यमाह

मध्यगतिज्ञं वीक्ष्य श्रीषेणार्यभटविष्णुचन्द्रज्ञाः ।

सदसि न भवन्त्यभिमुखाः सिंहं दृष्ट्वा यथा हरिणाः ॥ ६३ ॥

वि. भा.—मध्यगतिज्ञं (मध्यग्रहानयनवेत्तारं) वीक्ष्य (दृष्ट्वा) श्रीषेणार्यभटविष्णुचन्द्रोक्तानां मध्यग्रहानयनानां ज्ञातारः सदसि (सभायां) अभिमुखा (संमुखाः) न भवन्ति, यथा सिंहं दृष्ट्वा हरिणास्तदभिमुखा न भवन्तीत्यनेन ब्रह्मगुप्तेन स्वकीयमध्यग्रहानयनस्य वास्तवत्वं श्रीषेणार्यभटादीनामाचार्याणां मध्यग्रहानयनस्यावास्तवत्वं कथ्यतेऽथदितद्व्याजेन स्वप्रशंसां क्रियत इति ॥ ६२ ॥

अब अपनी प्रशंसा को कहते हैं

हि. भा.—हमारे मध्यग्रहानयन के समझने वाले को देखकर श्रीषेण-आर्यभट-विष्णु-चन्द्र इन आचार्योक्त मध्यग्रहानयन को समझने वाले सभा में उनके (हमारे मध्यग्रहानयन को समझने वालों के) सम्मुख नहीं होते हैं जैसे सिंह को देखकर हरिण उसके सम्मुख नहीं होता है । इससे आचार्य (ब्रह्मगुप्त) अपने मध्यग्रहानयन के वास्तवत्व और श्रीषेण-आर्यभट आदि आचार्योक्त मध्यग्रहानयन के अवास्तवत्व को कहते हैं अर्थात् इस व्याज से अपनी प्रशंसा करते हैं इति ॥ ६३ ॥

इदानीं मध्यमाधिकारोपसंहारमाह

अब स्पष्टीकरणादि सब ग्रहगणितों के ज्यागणित के अधीन होने के कारण पहले
अर्धज्या को कह कर उत्क्रमज्या को कहते हैं

हि. भा.—वृत्त परिधि के चतुर्थांश में २२५', २ × २२५', ३ × २२५'.....
चापों की चौबीस क्रमज्यायें और उत्क्रमज्यायें हैं जो संस्कृत विज्ञान भाष्य में लिखी गई हैं,
उन्हीं को यहाँ भी देखिए । चौबीस अंश की ज्या परमक्रान्तिज्या है, इनकी उपयोगिता
बहुत स्थानों में होने के कारण उसकी संख्या १३२६ पठित की गई है इति ॥ ३-६॥

उपपत्ति

वृत्त परिध्यांश ३६० के चतुर्थांश ९०° में चौबीस संख्यक क्रमज्यायें और उत्क्रमज्यायें

$$\left(\frac{९० \times ६०}{२४} = २२५' = \text{प्रथमचाप } २२५', २ \times २२५', ३ \times २२५' \dots २४ \times २२५' \right)$$

चापों की ज्योत्पत्तिविधि से ३२७० तुल्य त्रिज्या में आचार्य ने लाकर पाठ किया है, जैसे
भास्कराचार्य के मत में ३४३८ त्रिज्या में स्वल्पान्तर से प्रथमज्या = २२५,
तब अनुपात करते हैं यदि ३४३८ तुल्य त्रिज्या में २२५ तुल्य प्रथमज्या
पाते हैं तो ३२७० त्रिज्या में क्या, इस अनुपात से आचार्योक्त प्रथमज्या आती है,
 $\frac{२२५ \times ३२७०}{३४३८} = \text{आचार्योक्त प्रथमज्या, यहां हर और भ.ज्य में ६ इससे अपवर्तन करने से}$

$$\frac{२५ \times ३२७०}{३८२} = \frac{२५ \times १६३५}{१६१} = \frac{४०८७५}{१६१} = २१४ \frac{१}{१६१} = २१४ \text{ स्वल्पान्तर से आचार्योक्त}$$

प्रथमज्या, इसी तरह अवशिष्ट (द्वितीयादि) क्रमज्यायें और उत्क्रमज्यायें आती हैं, पठित-
ज्यायों से ज्यासाधन विधि से चौबीस अंश परमक्रान्त्यांश की ज्या साधन करने से १३२६
एतत्तुल्य होती है । सिद्धान्तशिरोमणि की टिप्पणी में संक्षेपक पठितज्याओं में पृष्ठज्या आती

से उससे पूर्व और अग्रिम (पृष्ठज्या और अग्रज्या) ज्याओं के घातानयन करके उस घात में पृष्ठज्या से भाग देने से अग्रिमज्या होती है और अग्रज्या से भाग देने से पृष्ठज्या होती है, दिखलाते हैं जैसे इष्टचाप=इ, प्रथमचाप=प्र, ज्या (इ-प्र)=पृष्ठज्या ज्या (इ+प्र)=अग्रज्या, दोनों के घात करने से ज्या (इ-प्र)×ज्या (इ+प्र)=पृष्ठज्या ×अग्रज्या

चापयोरिष्टयोर्दोर्ज्यो मिथः कोटिज्यकाहते इत्यादि से

$$\frac{(\text{ज्या}^2\text{इ} \times \text{कोज्या}^2\text{प्र} - \text{ज्या}^2\text{प्र} \times \text{कोज्या}^2\text{इ})}{\text{त्रि}^2} \times \frac{(\text{ज्या}^2\text{इ} \times \text{कोज्या}^2\text{प्र} + \text{ज्या}^2\text{प्र} \times \text{कोज्या}^2\text{इ})}{\text{त्रि}^2} = \text{योगान्तर}$$

घात वर्गान्तर के बराबर होता है, इस नियम से $\frac{\text{ज्या}^2\text{इ} \times \text{कोज्या}^2\text{प्र} - \text{ज्या}^2\text{प्र} \times \text{कोज्या}^2\text{इ}}{\text{त्रि}^2} =$

$$\frac{\text{ज्या}^2\text{इ} (\text{त्रि}^2 - \text{ज्या}^2\text{प्र}) - \text{ज्या}^2\text{प्र} (\text{त्रि}^2 - \text{ज्या}^2\text{इ})}{\text{त्रि}^2} =$$

$$\frac{\text{ज्या}^2\text{इ} \times \text{त्रि}^2 - \text{ज्या}^2\text{इ} \times \text{ज्या}^2\text{प्र} - \text{ज्या}^2\text{प्र} \times \text{त्रि}^2 + \text{ज्या}^2\text{प्र} \times \text{ज्या}^2\text{इ}}{\text{त्रि}^2} =$$

$$\frac{\text{ज्या}^2\text{इ} \times \text{त्रि}^2 - \text{ज्या}^2\text{प्र} \times \text{त्रि}^2}{\text{त्रि}^2} = \frac{\text{त्रि}^2 (\text{ज्या}^2\text{इ} - \text{ज्या}^2\text{प्र})}{\text{त्रि}^2} = \text{ज्या}^2\text{इ} - \text{ज्या}^2\text{प्र} = \text{पृष्ठज्या} \times$$

अग्रज्या, ३४३८ त्रिज्या में स्वल्पान्तर से ज्या^२प्र=५०५६० ∴ ज्या^२इ-५०५६०=

पृष्ठज्या × अग्रज्या इसलिए $\frac{\text{ज्या}^2\text{इ}-५०५६०}{\text{पृष्ठज्या}} = \text{अग्रज्या}$, वा $\frac{\text{ज्या}^2\text{इ}-५०५६०}{\text{अग्रज्या}} = \text{पृष्ठज्या}$,

इस से 'ज्यावर्गात्तरमाक्षाभ्रवाणोनात् इत्यादि' संशोधकोक्त उपपन्न हुआ ।

यहाँ आचार्योंक्त प्रथमज्या वश से पृष्ठज्या और अग्रज्या के घात से पूर्ववत् पृष्ठज्या और अग्रज्या का ज्ञान हो जायगा । संशोधकोक्त प्रकार का खण्डन किसी ने अधोलिखित युक्ति से किया है, ज्या(इ-प्र)×ज्या (इ+प्र)=पृष्ठज्या×अग्रज्या=ज्या^२इ-ज्या^२प्र; यहाँ

यदि इष्टचा=प्रवा तब ज्या^२इ-ज्या^२प्र=० × अग्रज्या ∴ $\frac{\text{ज्या}^2\text{इ}-\text{ज्या}^2\text{प्र}}{0} = \text{अग्रज्या} =$

अनन्त; परन्तु इष्टचाप और प्रथमचाप के बराबर रहने से अग्रज्यामान अनन्त के बराबर नहीं होना चाहिए इसलिए यह प्रकार ठीक नहीं है । लेकिन यहाँ किसी ने जो खण्डन किया है वह ठीक नहीं है, संशोधकोक्त प्रकार ठीक ही है जैसे—

ज्या^२इ-ज्या^२प्र=पृष्ठज्या×अग्रज्या, यदि इष्टचाप=प्रथमचाप तब ज्या (इ-प्र)=०=पृष्ठज्या, इसलिए ज्या^२इ-ज्या^२प्र=०×अग्रज्या, परन्तु वर्गान्तर योगान्तर घात के बराबर होता है ।

$$\text{अतः (ज्याइ—ज्याप्र) (ज्याइ+ज्याप्र)} = ० \times (\text{ज्याइ+ज्याप्र}) = ० \times \text{अग्रज्या} \\ \therefore \frac{० \times (\text{ज्याइ+ज्याप्र})}{०} = \text{अग्रज्या} = \text{ज्याइ+ज्याप्र} = \text{अग्रज्या, लुप्तभिन्नसमीकरण}$$

से अग्रज्या का मान समीचीन ही आता है, अतः संशोधकोक्त प्रकार समीचीन ही है, यह सिद्ध हुआ ।

यहां म.म. सुधाकर द्विवेदी जी ने अग्रज्या और पृष्ठज्या के योग के सम्बन्ध से अग्रज्या के ज्ञानार्थ विधि दिखलायी है, जैसे इष्टचाप = इ। प्रथमचाप = प्र, ज्या (इ—प्र) = पृष्ठज्या ज्या (इ+प्र) = अग्रज्या तब ज्या (इ—प्र) + ज्या (इ+प्र) = पृष्ठज्या + अग्रज्या, चाप गेरिष्टयोर्दोर्ज्योभिथः कोटिज्यकाहते इत्यादि से $\frac{\text{ज्याइ} \times \text{कोज्याप्र} - \text{ज्याप्र} \times \text{कोज्याइ}}{\text{त्रि}} +$

$$\frac{\text{ज्याइ} \times \text{कोज्याप्र} + \text{ज्याप्र} \times \text{कोज्याइ}}{\text{त्रि}} = \frac{२ \text{ ज्याइ} \times \text{कोज्याप्र}}{\text{त्रि}} \\ = \frac{२ \text{ ज्याइ} (\text{त्रि—ज्याउप्र})}{\text{त्रि}} = २ \text{ ज्याइ} - \frac{२ \text{ ज्याइ} \times \text{ज्याउप्र}}{\text{त्रि}} = २ \left(\text{ज्याइ} - \frac{\text{ज्याइ} \times \text{ज्याउप्र}}{\text{त्रि}} \right)$$

$$= २ \left(\text{ज्याइ} - \frac{\text{ज्याइ}}{\frac{\text{त्रि}}{\text{ज्याउप्र}}} \right) = २ \left(\text{ज्याइ} - \frac{\text{ज्याइ}}{३४३८} \right)$$

$$= २ \left(\text{ज्याइ} - \frac{\text{ज्याइ}}{४६७} \right) = \text{पृष्ठज्या} + \text{अग्रज्या, अतः } २ \left(\text{ज्याइ} - \frac{\text{ज्याइ}}{४६७} \right) - \text{पृष्ठज्या} =$$

अग्रज्या ।

इससे द्विवेदी जी का सूत्र 'जीवा स्वसप्तारियुगांशहीना इत्यादि' जो संस्कृतोपपत्ति में लिखा गया है, उपपन्न हुआ । आचार्य (ब्रह्मगुप्त) के मत में त्रिज्या = ३२७०, इस त्रिज्या से भी प्रथमोत्क्रमज्या = ७ अतः पूर्वोक्त सूत्र से इनकी पठित ज्याओं में किसी इष्टज्या से अग्रज्या का ज्ञान पूर्ववत् होता है, इति ॥३-६॥

केषाञ्चिन्मतं तत्प्रकारश्च

वि. भा.—इष्टज्यातो या ज्या विशुद्धयन्ति ताः शोध्याः, ज्याशेषगुणिता-

स्तत्त्वयमा २२५ गतैष्या ज्यान्तरभक्ता लब्धं यत्संख्यका जीवा विशुद्धास्तासां पञ्च-
दशवर्गणां २२५ च घाते योज्यं तदेष्टचापं भवेदिति ॥११॥

अत्रोपपत्तिः

इष्टज्यातो यत्संख्यका ज्या विशुद्धयन्ति ताः शोध्याः शेषा (गतज्येष्टज्ययो-
रन्तरात्) दनुपातो 'यदि गतैष्यज्यान्तरेण २२५ तत्तुल्यं चापं लभ्यते तदा गतज्येष्ट-
ज्ययोरन्तरेण किमिति' यत्लब्धं तद्विशुद्धज्यासंख्यागुणिततत्त्वादि २२५ मिते योज्यं
तदेष्टचापं भवेदित्येतदर्थमिष्टज्यानयने लिखितं क्षेत्रं विलोकयामित्यत्राप्यनुपातेऽप्य-
नौचित्यं पूर्ववदेव बोध्यमिति ॥११॥

अब ज्या से चापानयन करते हैं

हि. भा.—इष्टज्या में जितनी ज्यायें घटें उनको घटा देना, ज्याशेष और दो सौ
पच्चीस २२५ के घात में गतज्या और एष्यज्या के अन्तर से भाग देने से जो लब्धि हो
उसका विशुद्धज्या संख्यागुणित दो सौ पच्चीस २२५ में जोड़ने से इष्टचाप होता है,
इति ॥११॥

उपपत्ति

इष्टज्या में जितनी ज्यायें घटें घटा देना, शेष (गतज्या और इष्टज्या के अन्तर) से
अनुपात 'यदि गतज्या और एष्यज्या के अन्तर में दो सौ पच्चीस २२५ चाप पाते हैं तो गतज्या
और इष्टज्या के अन्तर में क्या' से जो लब्धि आती है उसको विशुद्धज्या गुणित दो सौ
पच्चीस २२५ में जोड़ने से इष्टज्या होती है। इसके लिये इष्टज्यानयन में लिखे हुए क्षेत्र को
देखना चाहिये। यहाँ भी अनुपात में अशुद्धता पूर्ववत् समझनी चाहिये, इति ॥११॥

अत्र विशेषो विचारः

भास्कराचार्यास्तु प्राचीनोक्तदिशा ज्यानयनं ३४३८ त्रिज्यायां विहितवन्तः ।
किन्तु खार्कव्यासार्धवृत्ते दशभिरंशैर्ज्या विवाय तदन्तरेण वृत्तपादे नवलघुज्याखण्डानि
प्रोचुः । तत्राभीष्टज्यानयने यथोक्तदिशा त्रैराशिकक्रियया जीवायां महत्स्थौल्यमापद्यते
तदर्थं स्फुटभोग्यखण्डानयनं विहितं भास्कराचार्यैः ।

तद्यथा । कल्प्यतेऽभीष्टचापम् = चा, यस्य जीवा साधनीया । दशभक्तचापं
गतसंज्ञकम् = गशेषम् = शे. प्रथमचापम् प्र ।

अत्र ग—प्र = पूर्वचापम्, ग + प्र = अग्रचापम्

∴ पूर्वज्या = $\frac{\text{ज्याग. कोज्याप्र} - \text{कोज्याग. ज्याप्र}}{\text{त्रि}}$ = ज्यापू.

$$\text{अग्रज्या} = \frac{\text{ज्याग. कोज्याप्र} + \text{कोज्याग. ज्याप्र}}{\text{त्रि}} = \text{ज्याश्र}$$

अत्र पूर्वज्यकायाः गतज्यकायां विशोधनेन गतखण्डं तथा अग्रज्यकायां गतज्यां विशोध्य भोग्यखण्डं भवतीत्यतः ।

$$\text{गतखण्डम्} = \text{गखं} = \frac{\text{ज्याग (त्रि—कोज्याप्र)} + \text{कोज्याग. ज्याप्र}}{\text{त्रि}}$$

$$\text{एवं भोग्यखण्डम्} = \text{भोखं} = \frac{\text{कोज्या. ज्याप्र—ज्याग (त्रि—कोज्याप्र)}}{\text{त्रि.}}$$

गतप्यखण्डयोर्योगान्तराभ्याम्—

$$\text{गखं} + \text{भोखं} = \frac{२ \text{ कोज्याग. ज्याप्र}}{\text{त्रि}}$$

$$\therefore \frac{\text{गखं} + \text{भोखं}}{२} = \frac{\text{कोज्याग. ज्याप्र}}{\text{त्रि}} \dots \dots \dots (१)$$

$$\text{एवं } \frac{\text{गखं—भोखं}}{२} = \frac{\text{ज्याग (त्रि—कोज्याप्र)}}{\text{त्रि}}$$

$$= \frac{\text{ज्याग. उज्याप्र}}{\text{त्रि}} \dots \dots \dots (२)$$

अथ ग + शे = इष्टचापम् = चा ।

$$\therefore \text{ज्याचा} = \frac{\text{ज्याग. कोज्याशे} + \text{कोज्याग. ज्याशे}}{\text{त्रि}}$$

अत्र शेपचापस्य दशभिरंशै रत्नत्वतः

$$\text{ज्याशे} = \frac{\text{ज्याप्र. शे}}{१०}, \therefore \text{ज्या}^३\text{शे} = \frac{\text{ज्या}^३\text{प्र. शे}^३}{१०२}$$

$$\therefore \text{कोज्या}^३\text{शे} = \text{त्रि}^३ - \frac{\text{ज्या}^३\text{प्र. शे}^३}{१०२}$$

मूलेनासन्नमानेन—

$$\text{कोज्याशे} = \text{त्रि} - \frac{\text{ज्या}^३\text{प्र. शे}^३}{\text{त्रि. १०२}} \text{ स्वल्पान्तरादग्रिमावयवत्यागात् ।}$$

यदि शे = प्र = १०

$$\text{कोज्याप्र} = \text{त्रि} - \frac{\text{ज्या}^2 \text{प्र}}{\text{त्रि}}$$

$$\therefore \frac{\text{ज्या}^2 \text{प्र}}{\text{त्रि}} = \text{त्रि} - \text{कोज्याप्र} = \text{प्रथमोत्क्रमज्या} = \text{उज्याप्र}$$

$$\therefore \text{कोज्याशे} = \text{त्रि} - \frac{\text{उज्याप्र. शे}^2}{१०२}$$

$$\therefore \frac{\text{उज्याप्र. शे}^2}{१०२} = \text{त्रि} - \text{कोज्याशे} = \text{उज्याशे}$$

अथ पूर्वानीतचापज्यायां गतज्याया विशोधनेन

$$\text{ज्यान्तरम्} = \frac{\text{कोज्याग. ज्याशे}}{\text{त्रि}} \therefore \frac{\text{ज्याग. (त्रि - कोज्याशे)}}{\text{त्रि}}$$

$$= \frac{\text{कोज्याग. ज्याप्र. शे}}{\text{त्रि} \times १०} \therefore \frac{\text{ज्याग. उज्याप्र. शे}^2}{\text{त्रि. १०२}}$$

$$= \frac{\text{कोज्याग. ज्याप्र. शे}}{\text{त्रि}} \cdot \frac{१०}{१०} \therefore \frac{\text{ज्याग. उज्याप्र. शे}^2}{\text{त्रि. १०२}}$$

अत्र (१) (२) समीकरणाभ्यामुत्थापनेन—

$$\text{ज्यान्तरम्} = \frac{\text{गखं} + \text{भोखं}}{२} \cdot \frac{\text{शे}}{१०} - \frac{\text{गखं} - \text{भोखं}}{२} \cdot \frac{\text{शे}^2}{१०२}$$

$$= \frac{\text{शे}}{१०} \left(\frac{\text{गखं} + \text{भोखं}}{२} - \frac{(\text{गखं} - \text{भोखं}) \text{शे}}{२०} \right)$$

अत्र कोष्ठकान्तर्गतखण्डं यदि भोग्यखण्डं मन्यते तर्हि प्रागुक्तानुपातेन वास्तवमेव ज्यान्तरं समागच्छतीति “यातैष्ययोः खण्डकयोर्विशेषः शेषांशनिघ्नो नखहृदित्यादि” भास्करोक्तं समीचीनमेव स्यात् व्यर्थं दुराग्रहेण प्रखण्डितं कमला-करेण ।

इदानीं मन्दशीघ्रकेन्द्रयोः केन्द्रभुजकोटिज्ययोश्च परिभाषामाह

मध्याद्विशोध्य मन्दं शीघ्रात्संशोध्य मध्यमं केन्द्रम् ।

अयुजि गतयेययोर्युजि पदेऽन्यथा बाहुकोटिज्ये ॥६२॥

व० म०.—इदानीं मन्दशीघ्रकर्मणोः केन्द्रकरणाधार्यर्धेनाह। अत्र करणागतो देशान्तरफलेन संस्कृतो मध्य उच्यते । मन्दस्फुटञ्च मध्यं भौमादीनां तेनायमर्थः मध्याद्विशोध्य मन्दं मध्याद् ग्रहात्स्वमन्दोच्चं विशोध्य केन्द्रं भवति । शीघ्रोच्चात् संशोध्य मध्यमं मन्दफलं स्फुटं शीघ्रकेन्द्रं भवति । केन्द्रशब्देन मध्यमुच्यते । तेन कक्षामण्डले प्रथमं केन्द्रं मन्दनीचोच्चवृत्तमध्यं द्वितीयं केन्द्रं शीघ्रनीचोच्चवृत्तमध्यं यथा न्यस्तेषु कक्षामण्डलप्रतिमण्डलादिषु कक्षामण्डले मध्यग्रहा चिह्नेत् । तत्प्रदेशे नीचोच्चवृत्तं मध्ये कृत्वा प्रदर्शयेत् तद्यथा मेपादेः प्रभृति । कक्षामण्डले यावतो राशिभागादयो भुक्ताः ग्रहास्तेभ्यः स्वमन्दोच्चभुक्ताः राशिभागादीन्विशोध्य शोधयेत् राशिभागादयस्तावद्भिर्मन्दोच्चभागावधेस्तन्मन्दोच्चनीचवृत्तमध्यं वर्तते । अत एव तदन्तरकराश्यादिकं केन्द्रं मध्यमुच्यते । स च रेखातस्तावत्प्रदेशे केन्द्रस्याग्रतो गतत्वात् । स्वमन्दोच्चात् शीघ्रगतिर्यतोऽतो ग्रहात् मन्दोच्चं विशोध्यतेऽधिकभुक्तिपार-ज्ञानाय स्वशीघ्रोच्चान्मन्दो ग्रहः अतएव शीघ्रात् ग्रहो विशोध्यते, तदन्तरपरिज्ञा-नाय क्रियति दूरे राशिभागाधिके ग्रहोऽवलंबित इति । यावति च प्रदेशे राशिभागा-दिके स्वशीघ्रोच्चरेखातो ग्रहपश्चादवलम्बितः कक्षामण्डले तावति दूरे शीघ्रनीचो-च्चवृत्तमध्ये वर्तते । अतएव तदन्तरकं शीघ्रकेन्द्रमुच्यते ।

अत्रोपपत्तिः

अथ भूकेन्द्रान्मन्दप्रतिवृत्तस्य शीघ्रप्रतिवृत्तस्य च यो हि दूरतरप्रदेशोऽर्थादु-च्चरेखा (वधितभूकेन्द्रग्रहगोलकेन्द्रगतरेखा) मन्दप्रतिवृत्तसम्पातस्तथोच्चरेखाशीघ्र-प्रतिवृत्तसम्पातश्च मन्दोच्चं शीघ्रोच्चं चेति, मन्दप्रतिवृत्ते यत्र गणितागतो मध्यमग्रहोऽस्ति भूकेन्द्रात्तद्गता रेखा शीघ्रप्रतिवृत्ते यत्र लगति तत्र मन्दस्पष्टग्रहः । मन्दोच्चान्मध्यमग्रहावधिमन्दप्रतिवृत्ते मन्दकेन्द्रसंज्ञकम् । शीघ्रोच्चान्मन्दस्पष्ट-ग्रहावधिशीघ्रप्रतिवृत्ते शीघ्रकेन्द्रसंज्ञकम् । मध्यमग्रहगतितो मन्दोच्चगतेरल्पत्वात् मध्यमग्रह—मन्दोच्च=मन्दकेन्द्रम्, तथा शीघ्रोच्चगतेर्मन्दस्पष्टग्रहगतेरल्पत्वात् शीघ्रोच्च—मन्दस्पष्ट=शीघ्रकेन्द्रम् । ग्रहगोलकेन्द्रादुच्चरेखोपरि लम्बरेखा कार्या तदैताभ्यां रेखाभ्यां मन्दप्रतिवृत्तस्य समानि चत्वारि खण्डानि नवत्यंशमितानि भव-न्ति, उच्चरेखातः (उच्चबिन्दुतो वा) सव्यक्रमेण चत्वारि पदानि कल्पानि, प्रथमपदे मन्दप्रतिवृत्ते यत्र ग्रहस्तस्योच्चरेखायाश्चान्तरं भुजज्या । ग्रहात्तिर्यग्रेखो (मन्दगोल-केन्द्रादुच्चरेखोपरिलम्बरेखा) परिलम्बरेखा भुजकोटिज्या, यथा-यथा ग्रहो पदान्ता-भिमुखं गच्छेत्तथा तथा भुजज्योपचीयते, भुजकोटिज्या चापचीयते, पदान्ते भुजज्या परमा त्रिज्या समा भुजकोटिज्यायाश्चाभावः ततोऽग्रे द्वितीयपदे ग्रहो यथा-यथाऽग्रतो गच्छति तथा-तथा भुजज्याऽपचीयते, भुजकोटिज्योपचीयते द्वितीयपदान्ते भुजज्याऽ-भावः, भुजकोटिज्या च परमा त्रिज्या समा भवत्यतोऽयुजि गतयेययोर्युजि पदेऽन्यथा बाहुकोटिज्ये इत्याऽचार्योक्तं युक्तियुक्तं संगच्छते तृतीये चतुर्थे पदेऽप्येवमेव विचारः कार्यः । सूर्यसिद्धान्ते 'ग्रहं संशोध्य मन्दोच्चात्तथा शीघ्राद्विशोध्य चेत्यादिना, मध्यम-

मन्दोच्चाद्विशोध्य शेषं मन्दकेन्द्रं कथ्यते भगवता सूर्याशुतुषेण, अन्यत्मर्वमात्रा-
योक्तवदेवास्ति सिद्धान्तखेत्रे श्रीपतिना सिद्धान्तशिरोमणी भास्कराचार्येण
चाऽऽचार्योक्तमेव कथ्यत इति ॥१२॥

अब मन्दकेन्द्र और शीघ्रकेन्द्र की तथा केन्द्रज्या-और
केन्द्र कोटिज्या की परिभाषा कहते हैं

हि. भा.—मध्यमग्रह में मन्दोच्च को घटाने से शेष मन्दकेन्द्र होता है, शीघ्रोच्च में
मन्द स्पष्ट ग्रह को घटाने से शेष शीघ्र केन्द्र होता है, विपम पद में गत चाप की ज्या
भुजज्या कहलाती है, गम्य (एष्य) चाप की ज्या कोटिज्या कहलाती है, सम पद से इसके
विपरीत अर्थात् गम्यचापज्या भुजज्या और गतचापज्या कोटिज्या होती है इति ॥१२॥

उपपत्ति

भूकेन्द्र से मन्द प्रनिवृत्त और शीघ्र प्रतिवृत्त का जो दूरतर प्रदेश (अर्थात् उच्चरेखा
और वर्धित भूकेन्द्र ग्रहगोलकेन्द्रगतरेखा के योग बिन्दु) हैं वे क्रमशः मन्दोच्च और शीघ्रोच्च
कहलाते हैं, मन्द प्रतिवृत्त में गणितागत मध्यम ग्रह जहाँ है भूकेन्द्र से तद्गत रेखा शीघ्र-
प्रतिवृत्त में जहाँ लगती है वही मन्दस्पष्ट ग्रह है, मन्दोच्च से मध्यमग्रहपर्यन्त मन्द प्रति-
वृत्तीय चाप मन्दकेन्द्र है, शीघ्रोच्च से मन्दस्पष्टग्रहपर्यन्त शीघ्र प्रतिवृत्तीय चाप शीघ्र-
केन्द्र है, मन्दोच्च की गति मध्यमग्रह गति से अल्प होने के कारण मध्यमग्रह—मन्दोच्च =
मन्दकेन्द्र, तथा मन्दस्पष्टग्रह की गति से शीघ्रोच्च गति के अधिक होने के कारण शीघ्रोच्च
—मन्दस्पष्टग्रह = शीघ्रकेन्द्र, ग्रहगोल केन्द्र से उच्चरेखा के ऊपर लम्बरेखा करने से उच्च-
रेखा और लम्ब रेखा से मन्द प्रतिवृत्त के समान चार खण्ड (नवत्यंश के बराबर) होते हैं,
मन्दोच्च से सव्य क्रम से चार पद कल्पना करना ।

प्रथम पद में मन्द प्रतिवृत्त में जहाँ ग्रह है उसका और उच्चरेखा का लम्बरूप अन्तर
भुजज्या है, ग्रह से तिर्यक् रेखा (मन्दगोल केन्द्र से उच्चरेखा के ऊपर लम्ब रेखा) के ऊपर
लम्बरेखा कोटिज्या है, ग्रह ज्यों-ज्यों पदान्ताभिमुख जाते हैं त्यों-त्यों भुजज्या उपचीयमान
होती है और कोटिज्या अपचीयमान होती है, पदान्त में भुजज्या परम (त्रिज्यातुल्य) होती
है और कोटिज्या का अभाव होता है, उससे आगे द्वितीय पद में ग्रह ज्यों-ज्यों आगे जाते हैं
त्यों-त्यों भुजज्या अपचीयमान होती है और कोटिज्या उपचीयमान होती है, पदान्त में
भुजज्या का अभाव होता है और कोटिज्या परम (त्रिज्या तुल्य) होती है इसलिए “अयुजि
गतयेययोर्युजिपदेज्यया वाहुकोटिज्ये” यह आचार्योक्त युक्तियुक्त है, इसी तरह तृतीय पद और
चतुर्थ पद में भी विचार करना चाहिए, सूर्य सिद्धान्त में ‘ग्रहं संशोध्य मन्दोच्चात्तथा शीघ्राद्
विशोध्य च’ इत्यादि से मन्दोच्च ही में मध्यम ग्रह को घटाकर शेष को मन्द केन्द्र कहते हैं,
और सब कुछ आचार्योक्तवत् ही है, सिद्धान्तखेत्तर में श्रीपति और सिद्धान्तशिरोमणि में
भास्कराचार्य भी आचार्योक्त ही को कहते हैं इति ॥१२॥

इदानीं स्पष्टपरिध्यानयनमाह

त्रिज्याहता भुजज्या युगयुक्परिधिद्वयान्तरगुणाप्त्या ।

युग्मान्तपरिधिरधिको हीने हीनोऽधिके स्पष्टः ॥१३॥

वा. भा.—इदानीं शुक्रमन्दशीघ्रकर्मणोः परिधिसंस्कारार्थमार्यामाह । मन्दोच्चनीचवृत्तस्य परिधिभागाः सितस्य विषमान्ते नवचेत्यादिना ये परिधयः पठिताः मन्दपरिधिप्रथमपदान्ते तृतीयपदान्ते च नवरसयमाः, द्वितीयचतुर्थपदान्तयोरष्टभागाः द्वितीयपदान्ते चतुर्थपदान्ते चैकादशभागाः शीघ्रपरिधिप्रथमतृतीयपदान्तयोरग्निरसयमा भागा । एवं स्थिते चाम्यन्तरे परिधेः साधनायेदमार्यसूत्रं त्रैराशिकात्मकं तद्यथा त्रिज्याहता कासौ भुजज्या किं भूता, युगयुक्परिधिद्वयान्तरगुणा च शीघ्रकर्मणोरपि ततोऽवाप्तिः तथा वाप्त्याधिको युग्मान्तरपरिधिः कर्तव्यः । यदि विषमान्तरपरिधेरूनः । अथ युग्मान्तरपरिधिरधिकस्तदा भागावाप्त्या हीनः कार्यः स मन्दनीचोच्चवृत्तस्य शीघ्रनीचोच्चवृत्तस्य च परिधिः स्फुटो भवति तेन वक्ष्यमाणविधिना फलानयनम् । अत्र मन्दप्रतिमण्डलोच्चप्रदेशे नीचोच्चवृत्तस्यैकादशकः परिधिः तत्क्रमेणोपचीयते । यावत्प्रथमं पदान्तं तत्र नवपरिधिः । तथा तत्र फलोपलब्धैस्ततः परं पुनरप्यपचीयते । यावत्प्रतिमण्डलार्धचक्रं तत्रैकादशको मन्दनीचोच्चपरिधिहृच्चप्रदेशवत्त्रापि तथैव फलोपलब्धेः प्रथमद्वितीयपदयोस्त्रिचतुर्थपदे व्याख्याते । अथवान्तरे त्रैराशिकं यदि भुजज्या त्रिज्या यत्र तत्र परिध्यन्तरं द्वौ यत्र चेष्टौ भुजज्या तत्र किमिति लब्धेन युग्मान्तपरिधिरपचीयते । क्रमेण विषमान्तेन भविष्यन्ति । एवं शेषपदेषु मन्दकर्मणि योज्यं । शीघ्रकर्मणि परिधिसंस्कारो विपरीतः वासनावैपरीत्यात् तत्र यदि भुजज्या त्रिज्या तुल्यया पञ्चभागाः परिधिरन्तरं तदेष्टभुजज्या किमिति फलेनोपचीयते । युग्मान्तरं परिधिर्यत्रोपचयक्रमेण विषमान्तोऽग्निरसयमलसंख्यो भविष्यति, तथा स्थिते एतत् गोले छेद्यके वा प्रदर्शयेत् । एवं शुक्रस्य मन्दनीचोच्चवृत्तशीघ्रनीचोच्चवृत्तयो परिधौ संस्कार्यौ बुधगुरुशनीनां वक्ष्यमाणं यथा पठिता एवं परिधयः स्फुटाः मन्दशीघ्रयोरपि कुजस्यापि मन्दपरिधिर्यथा पठिता तच्छीघ्रपरिधेरपि संस्कारं वक्ष्यति शीघ्रस्फुटपरिधिनाप्तभागोना वेदजिनाः अंशोना इति स तथा एव स्फुटो भवति । इदानीं इष्टस्फुटः परिधिनाप्ता भागोना वेदजिना अंशौ, पूर्वानीतभुजकोटिभ्यां च भूमध्यप्रतिमण्डलस्थपारमार्थिकग्रहान्तरकरणभुजकोटिज्ये क्रियेते तत्करणमार्यामाह ।

वि. भा.—भुजज्या (केन्द्रज्या) युगयुक्परिधिद्वयान्तरगुणा (समविषमपदान्तपरिध्योरन्तरेण गुणा) त्रिज्याहता (त्रिज्याभक्ता) आप्त्या (लब्ध्या) युग्मान्तपरिधिः (समपदान्तपरिधिः) अधिकः कार्यो विषमपदान्तपरिधेः समपदान्तपरिधिमानेऽप्ये सति अधिके (विषमपदान्तपरिधेः समपदान्तपरिधिमानेऽधिके) लब्ध्या समपदान्तपरिधिर्हीनः कार्यस्तदा स्पष्टः परिधिर्भवेदिति ॥१३॥

अत्रोपपत्तिः

यदि त्रिज्यातुल्यया केन्द्रभुजज्याया समविषमपदान्तपरिध्योरन्तरं लभ्यते तदेष्टकेन्द्रभुजज्याया किमित्यनुपातेनागतं फलं (इष्टपरिध्यन्तरं) विषमपदान्तपरिधेः समपदान्तपरिधिमानस्याल्पत्वे समपदान्तीयपरिधिमाने योज्यं, विषमपदान्तपरिधेः समपदान्तपरिधिमानस्याधिक्ये समपदान्तीयपरिधिमाने वियोज्यं तदेष्टपरिधिः स्पष्टो भवेत् । सूर्यसिद्धान्तकारेण 'भोजयुग्मान्तरगुणा भुजज्या त्रिज्ययोद्धृतेत्यादिना' श्रीपतिना 'भोजयुक्परिधिजान्तरनिघ्नी दोज्यंकेत्यादिना' प्याचार्योक्तानुरूपमेव कथ्यत इति ॥१३॥

अब स्पष्टपरिध्यानयन को कहते हैं

हि. भा.—केन्द्रज्या को समपदान्तीय परिधि और विषमपदान्तीय परिधि के अन्तर से गुणाकर त्रिज्या से भाग देने से जो फल होता है उसको समपदान्तीय परिधि में जोड़ देना (यदि विषम पदान्त परिधि से समपदान्त परिधि अल्प हो तब), यदि विषम पदान्त परिधि से समपदान्त परिधि अधिक हो तब घटा देने से स्पष्ट परिधि होती है इति ॥१३॥

उपपत्तिः

यदि त्रिज्या तुल्य केन्द्र भुजज्या में सम-विषम पदान्तीय परिध्यन्तर पाते हैं तो इष्ट-केन्द्र भुजज्या में क्या इस अनुपात से जो फल आता है उसको विषम-पदान्त परिधि से सम-पदान्त परिधि के अल्प रहने से समपदान्तपरिधि में जोड़ने से इष्ट स्थानीय परिधि (स्पष्टपरिधि) होती है, विषम पदान्त परिधि से समपदान्त परिधि के अधिक रहने से समपदान्त परिधि में घटाने से स्पष्ट परिधि होती है । सूर्य सिद्धान्तकार 'भोजयुग्मान्तरगुणा भुजज्या त्रिज्ययोद्धृता इत्यादि से' तथा श्रीपति 'भोजयुक् परिधिजान्तरनिघ्नी' इत्यादि से आचार्योक्तानुसार ही कहते हैं । इति ॥१३॥

इदानीं भुजफलकोटिफलसाधनं स्पष्टां कोटिञ्चाह

मन्दकोटिफलम् । एवं शीघ्रकेन्द्रज्यादिवशेन शीघ्रभुजफलकोटिफले भवतः ।
उज = प्रथमपदम्, जय = द्वितीयपदम् । यप = तृतीयपदम् । उप = चतुर्थपदम् ।
जउप = मकरादिकेन्द्रम् । जयप = कर्क्यादिकेन्द्रम् । भूम + लम = त्रि + मन्दकोटिफल
= भूल = मन्दनीचोच्चवृत्तीयस्पष्टा कोटिः । एवं चतुर्थपदेऽपि भवति, द्वितीयतृतीय-
पदयोः त्रि—मन्दकोटिफ = मन्दनीचोच्चवृत्तीय स्पष्टा कोटिरिति भुजफलकोटिफल-
स्वरूपविन्यासेनैव तत्र स्फुटं भवत्येतावताऽऽचार्योक्तं सम्यगुपपद्यत इति ॥१४॥

अब भुजफल और कोटिफल के साधन तथा स्पष्टा कोटि को कहते हैं

हि. मा.—केन्द्रज्या और केन्द्र कोटिज्या को स्पष्ट परिधि से गुणा कर भांश ३६० से भाग देने से भुजफल और कोटिफल होता है । प्रथम पद और चतुर्थ पद (मकरादि केन्द्र) में त्रिज्या में कोटिफल को जोड़ने से स्पष्टा कोटि होती है, द्वितीय पद और तृतीय पद (कर्क्यादि केन्द्र) में त्रिज्या में कोटिफल को घटाने से स्पष्टा कोटि होती है । यहां मन्द-केन्द्रज्या, मन्दकेन्द्र कोटिज्या, और मन्द परिधि के सम्बन्ध से मन्दभुजफल और मन्द कोटि-फल होता है, तथा शीघ्रकेन्द्रज्या, शीघ्रकेन्द्र कोटिज्या और शीघ्रपरिधि के सम्बन्ध से शीघ्र भुजफल और शीघ्रकोटिफल होता है इति ॥१४॥

उपपत्ति

यहाँ संस्कृतोपपत्ति में लिखित (क) क्षेत्र को देखिये । भू = भूकेन्द्र, भू बिन्दु से त्रिज्या व्यासार्ध से वृत्त कक्षावृत्त होता है, न = ग्रहगोलकेन्द्र, न बिन्दु से उसी त्रिज्या व्यासार्ध से जो वृत्त होता है वह प्रतिवृत्त है, भून, = अन्त्यफलज्या भू, न बिन्दुओं से ऊर्ध्वाधर रेखा और तिर्यग्रेखायें कीजिये । उ = प्रतिवृत्त में उच्चस्थान । उ = कक्षावृत्त में उच्चस्थान । ग्र = प्रतिवृत्त में मध्यमग्रह । म = कक्षावृत्त में मध्यमग्रह । वर्धित भूम रेखा के ऊपर म बिन्दु से लम्ब = ग्रस = भुजफल, मल = कोटिफल, ग्रम = अन्त्यफलज्या, = रच = भून, भूम = त्रिज्या, ग्रश = केन्द्रज्या = भूर, ग्रच = केन्द्रकोटिज्या = मर भूमर, मग्रल दोनों त्रिभुज सजातीय हैं

इसलिए अनुपात करते हैं $\frac{\text{भूम} \times \text{ग्रम}}{\text{भूम}} = \frac{\text{केन्द्रज्या} \times \text{अन्त्यफज्या}}{\text{त्रि}} = \text{ग्रल} = \text{भुजफल}$

$= \frac{\text{केन्द्रज्या} \times \text{परिधि}}{३६०}$ क्योंकि $\frac{\text{अन्त्यफज्या}}{\text{त्रि}} = \frac{\text{परिधि}}{३६०}$, म बिन्दु को केन्द्र मानकर 'मग्र' अन्त्य-

फलज्या व्यासार्ध से जो वृत्त बनता है वही नीचोच्चवृत्त है उसी को स्पष्ट परिधि कहते हैं ।

तथा $\frac{\text{मर} \times \text{ग्रम}}{\text{भूम}} = \frac{\text{केन्द्रकोज्या} \times \text{अन्त्यफज्या}}{\text{त्रि}} = \text{लम} = \frac{\text{केन्द्रकोज्या} \times \text{परिधि}}{३६०} = \text{कोटिफल, उज}$

= प्रथमपद, जय = द्वितीयपद, यप = तृतीयपद, उप = चतुर्थपद, जउप = मकरादिकेन्द्र, जयप = कर्पादिकेन्द्र, भूम + लम = भूल = त्रि + कोटिफल = नीचोच्चवृत्तीय स्पष्टा कोटि, इसी तरह चतुर्थ पद में भी होता है, द्वितीय और तृतीय पद में त्रि = कोटिफल = नीचोच्चवृत्तीय स्पष्टा कोटि यह भुजफल और कोटिफल फलस्वरूप के विन्यास ही से स्पष्ट होता है, इससे आचार्योक्त उपपन्न होता है, सिद्धान्तशिरोमणि में भास्कराचार्य 'स्वेनाहते परिधिना' इत्यादि से, तथा त्रिज्या तथा कोटिफलेन युक्ता हीना च इससे इसी विषय को कहते हैं । सिद्धान्तशेखर में भी 'स्फुटनिजपरिणाहभुण्ण दोःकोटिजीवे' इत्यादि से आचार्योक्त के अनुरूप ही कहा गया है इति ॥१४॥

अत्रोपपत्तिः

१४ तम श्लोकस्य संस्कृतोपपत्तिस्थक्षेत्रे भूज=करणं= $\sqrt{\text{ग्रल}^2 + \text{भूल}^2} = \sqrt{\text{भुजफल}^2 + \text{नाचाच्चवृत्तस्फुटो}^2}$, प्रथमपदे गतकेन्द्रांशानां ज्या स्वपरिधिगुणा भांशे ३६० भांज्या तदा पूर्वोक्तप्रकारागतं भुजफलमेव भवेत् । द्वितीयपदे एष्यांशानां ज्या गतोत्क्रमज्योनत्रिज्यातुल्या तदा पूर्ववदेव भुजफलम्

= $\frac{\text{परिधि (त्रि—गतकेन्द्रांशोत्क्रमज्या)}}{३६०}$, \therefore परमभुजफल

= $\frac{\text{परिधि (त्रि—गकेन्द्रज्या)}}{३६०}$ अर्थात्समपदे केन्द्रांशोत्क्रमज्यातो यत्फलं समागच्छे-

त्तेन हीनं परमं भुजफलं वास्तवं भुजफलं भवेत् । विषमपदे (प्रथमपदे तृतीयपदे च)

$\frac{\text{केन्द्रज्या} \times \text{परिधि}}{३६०} = \text{भुजफलम्, पदान्ते केन्द्रज्यायाः परमत्वात्तत्र भुजफलस्यापि}$

परमत्वं भवेत्। समपदे (द्वितीयपदे, चतुर्थपदे च), परम भुजफल

$\frac{\text{केउत्क्रमज्या} \times \text{परिधि}}{३६०} = \text{वास्तवभुजफल, पदान्ते भुजफलं शून्यं, अत्रोत्क्रमज्या-}$

गतं फलं परमे भुजफले ऋणं कार्यमिति चतुर्वेदाचार्यमतानुकूलोऽध्याहार इत्याचार्यसूत्रतो नाऽऽयातीति बोध्यं विज्ञैरिति ॥ १५ ॥

अब कर्णानयन को तथा प्रकारान्तर से भुजफलानयन को भी कहते हैं

हि. भा.—पूर्वानीतस्फुटकोटि और भुजफल के वर्गयोग का मूल लेने से कर्ण होता है। विषम पदों में केन्द्रज्या को स्पष्ट परिधि से गुणा कर भांश ३६ से भुजफल होता है, समपदों में केन्द्रांशोत्क्रमज्या को स्पष्ट परिधि से गुणा कर भांश ३६० से भाग देने से जो फल हो उसको परमभुजफल में घटाने से वास्तव भुजफल होता है, यह अध्याहार करना चाहिये श्लोक में 'मन्दे' शब्द का सम्बन्ध अगले श्लोक के साथ है इति ॥ १५ ॥

उपपत्ति

१४ वें श्लोक का संस्कृतोपपत्तिस्थ क्षेत्र देखिये, भूज = कर्ण = $\sqrt{\text{मल}^2 + \text{भूल}^2}$
 $= \sqrt{\text{भुजफल}^2 + \text{नीचोत्क्रमज्या}^2}$ प्रथम पद में गत केन्द्रांशज्या को स्पष्ट परिधि से गुणाकर भांश ३६० से भाग देने से पूर्व प्रकारागत ही भुजफल होता है। द्वितीय पद में एष्यांशज्या गतोत्क्रमज्योन त्रिज्या के बराबर होती है तब उससे पूर्ववत् भुजफल = परिधि (त्रि—गतकेन्द्रांशोत्क्रमज्या), अतः परम भुजफल—

त्रि

परिधि (त्रि—गतकेन्द्रांशोत्क्रमज्या) = वास्तव भुजफल अर्थात् सम पदों में केन्द्रांशोत्क्रमज्या

त्रि

से जो फल आवे उसको परमभुजफल में घटाने से वास्तव भुजफल होता है, विषमपद

(प्रथम पद, तृतीय पद) में $\frac{\text{केज्या} \times \text{परिधि}}{३६०} = \text{भुजफल; पदान्त में केन्द्रज्या परमत्व के}$

कारण परमभुजफल होता है, समपदों (द्वितीय पद चतुर्थ पद) में परम भुजफल—

$\frac{\text{के उत्क्रमज्या} \times \text{परिधि}}{३६०} = \text{वास्तव भुजफल; पदान्त में भुजफल शून्य होता है, यहाँ उत्क्रमज्या}$

से आये हुये फल को ऋण करना चाहिये, यह चतुर्वेदाचार्य के मतानुकूल अध्याहार करना होता है, ये बातें आचार्य (ब्रह्मगुप्त) के सूत्र से नहीं आती हैं, यह समझना चाहिये इति ॥ १५ ॥

वि. भा.—मन्दे (मन्दकर्मणि) पदक्रमेण पूर्वानीतफलानि क्षयघनघन-
क्षयाः स्युः । शीघ्रे (शीघ्रकर्मणि) अन्यथाऽर्थात् घनक्षयक्षयनानि स्युः । ततो

श्लोकाभ्यां ब्रह्मगुप्तोक्तं ‘तद्भुजफलकृतियोगान्मूलं कर्णः पदेष्वित्यादेः
क्षयघनघनक्षयास्तत्फलानीत्यादि’ श्लोकद्वयस्य पुनरुक्तीकरणमेव कृतमिति
विवेचकैर्विवेचनीयम् ॥ १६ ॥

अब पूर्वानीत फल के ऋणत्व और धनत्व को उससे संस्कार वश भुजफल को कहते हैं

हि. भा.—मन्दकर्म में पदक्रम से पूर्वानीत फल ऋण, धन, धन, ऋण होते हैं, शीघ्र कर्म में इससे भिन्न होता है अर्थात् पद क्रम से धन, ऋण, ऋण, धन होते हैं, इस कारण से धन, धन का योग धन होता है, ऋण, ऋण का योग ऋण होता है, और धन, ऋण का अन्तर संस्कार वश से भुजफल धनात्मक और ऋणात्मक होता है, धन और ऋण के तुल्यत्व से भुजफलाभाव (शून्य) होता है इति ॥ १६ ॥

उपपत्ति

प्रथम पद और द्वितीय पद मेषादि केन्द्र है, तथा तृतीय पद और चतुर्थ पद तुलादि केन्द्र है, मन्द कर्म में भुजफल के चाप के बराबर मन्द फल मेषादि केन्द्र में ऋण होता है और तुलादि केन्द्र में धन होता है, इसलिये प्रथम पद और द्वितीय पद में भुजफल ऋण होता है, तृतीय पद में और चतुर्थ पद में भुजफल धन होता है क्योंकि उससे मन्द फल धनात्मक उत्पन्न होते हैं, द्वितीय पद में पूर्वगित भुजफल = परम भुजफल — $\frac{\text{परिधि} \times \text{केन्द्रज्या}}{३६०}$,

धन और ऋण के विलोम से — परम भुजफल + $\frac{\text{परिधि} \times \text{केन्द्रज्या}}{३६०}$, इसी तरह चतुर्थ पद में

पूर्वगित भुजफल = परमभुज — $\frac{\text{परिधि} \times \text{केन्द्रज्या}}{३६०}$ धनात्मक, मेषादि केन्द्र में प्रथम पद के होने

के कारण प्रथम पद में भुजफल ऋण तथा तुलादि केन्द्र में तृतीय पद के होने के कारण वहां धन होता है, इस तरह पद क्रम से मन्द कर्म में फल ऋण, धन, धन, ऋण होते हैं, शीघ्र कर्म से इससे विलोम होता है क्योंकि शीघ्रकर्म में मेषादिकेन्द्र में शीघ्रफल धन होता है और तुलादिकेन्द्र में ऋण होता है इसी हेतु से वहां भुजफल भिन्न होता है, सिद्धान्त-शेखर में श्रीपति 'ऋणं क्रमादित्यादि, युतिः स्वयोः स्वं 'क्षययोः' इत्यादि संस्कृतोपपत्ति में लिखित श्लोकद्वय से आचार्योक्त 'तद्भुजफलकृतियोगात्' इत्यादि, 'क्षयधनधनक्षयास्तत्फलानि' इत्यादि श्लोकद्वय का पुनरुक्तीकरण ही किया है इति ॥ १६ ॥

वि. भा.—(तच्चापं मन्दभुजफलस्य चापं) मन्दफलं पूर्वसाधितफलयोर्योगान्तरवशात् धनं वा ऋणं भवति । तद्गुणितात् (पूर्वगितशीघ्रभुजफलेन गुणितात्) व्यासार्धात् (त्रिज्यातः) कर्णं (शीघ्रकर्णं) भक्ताद्यल्लब्धं तस्य धनुः (चापं) शीघ्रफलं भवतीति ॥१७॥

अत्रोपपत्तिः

तात्कालिककर्णाग्रीयमन्दभुजफलचापं मन्दफलं न भवितुमर्हति, पठितमन्द-कर्णाग्रीयभुजफलस्य चापं मन्दफलं भवति कथमित्युच्यते ।

उ = मन्दोच्चम् । ग्र = मन्दप्रतिवृत्ते ग्रहः । भू = भूकेन्द्रम् । ज = ग्रहगोलकेन्द्रम् ।
 भूज = मन्दान्त्यफलज्या । ग्रन = तात्कालिकान्त्यफलज्या = तच = भूज । भूग्र =
 तात्कालिकमन्दकर्णः । ग्रर = मन्दभुजफलम् । प बिन्दुतो भूर रेखायाः समान्तरा
 पग्र रेखा कार्या, प बिन्दुत एव ग्रन रेखायाः समान्तरा पश रेखा कार्या, भूग्र रेखा
 कार्या । पय = मन्दफलज्या, अथ भूग्रन, भूपश त्रिभुजयोः साजात्यान्

$$\frac{\text{ग्रन} \times \text{भूप}}{\text{भूग्र}} = \frac{\text{तात्कालिकान्त्यफलज्या} \times \text{त्रि}}{\text{तात्कालिकमन्दकर्ण}} = \text{पश} = \text{पठितान्त्यफलज्या} = \text{ग्रन},$$

अतोभूग्र = पठितमन्दकर्णः । ग्रग = पठितमन्दकर्णाग्रीयभुजफलम् = पय =
 मफलज्या ग्रर > पय वा तात्कालिकमन्दकर्णाग्रीयभुजफल > मन्दफलज्या
 अत एव मन्दभुजफलचापं मन्दफलं न भवितुमर्हति, किन्तु पठित-
 मन्दकर्णाग्रीयमन्दभुजफलचापं मन्दफलं भवितुमर्हत्यत आचार्योक्त 'तच्चापं
 मन्दफलं' मिदं न युक्तम् । सिद्धान्तशेखरे श्रीपत्यु 'दोः फलस्य च वतुः
 कलादिकं जायते मृदुफल नभः सदा' क्तमिदं 'मृदुदोः फलस्य चापं बुधा
 मन्दफलं वदन्ति' भास्करोक्तमिदं चाऽऽचार्योक्तानुरूपमेव । एवं $\frac{\text{शीघ्रभुजफल} \times \text{त्रि}}{\text{शीघ्रकर्ण}} =$

शीघ्रफलज्या, एतच्चापं शीघ्रफलं भवेत् । श्रीपतिना 'दोः फलत्रिगुणयोरभिघाता-
 त्कर्णलब्धधनुराशुफलं स्यात्' ऽप्यनेनाऽऽचार्योक्तानुरूपमेव कथ्यत इति ॥१७॥

अब मन्दफल और शीघ्रफल कहते हैं

हि. भा.—मन्द भुजफल का मन्दफल होता है, यह पूर्वसाधित फलद्वय के योग और
 अन्तर वश से घन वा ऋण होता है, पूर्वागत शीघ्रभुजफल को त्रिज्या से गुणा कर शीघ्र
 कर्ण से भाग देने से जो लब्धि होती है उसका शीघ्रफल होता है ॥ १७ ॥

उपपत्ति

यहां संस्कृतोपपत्ति में लिखित (क) क्षेत्र को देखिये । तात्कालिक मन्दकर्णाग्रीय
 भुजफल का चाप मन्दफल नहीं होता है, किन्तु पठित मन्दकर्णाग्रीय भुजफल का चाप
 मन्दफल होता है इसके लिये अधोलिखित युक्ति है । उ = मन्दोच्च, ग्र = मन्दप्रतिवृत्त में
 ग्रह, भू = भूकेन्द्र, ज = ग्रहगोलकेन्द्र, भूज = मन्दान्त्यफलज्या, ग्रन = तात्कालिकमन्दा-
 न्त्यफलज्या = तच = भूज, भूग्र = तात्कालिकमन्दकर्ण, ग्रर = मन्दभुजफल, प बिन्दु से भूर
 रेखा की समान्तरा रेखा पग्र, प बिन्दु से ग्रन रेखा की समान्तरा पश रेखा कीजिये, भूग्र
 रेखा कीजिये पय = मन्दफलज्या, भूग्रन, भूपश दोनों त्रिभुज सजातीय हैं इसलिये अनुपात

करते हैं । $\frac{\text{ग्रन} \times \text{भूप}}{\text{भूग्र}} = \text{पश} = \frac{\text{तात्कालिकमन्दान्त्यफलज्या} \times \text{त्रि}}{\text{तात्कालिकमन्दकर्ण}} = \text{पठितमन्दान्त्यफलज्या} =$

१. ग्रन, अतः भूग्र = पठितमन्दकर्ण, ग्रग = पठितमन्दकर्णाश्रीय भुजफल = पय = मन्दफलज्या, ग्रर > पय वा तात्कालिकमन्दकर्णाश्रीय भुजफल > मन्दफलज्या इसलिये तात्कालिक मन्दकर्णाश्रीय भुजफल का चाप मन्दफल नहीं हो सकता है किन्तु पठितमन्दकर्णाश्रीय भुजफल का चाप मन्दफल के बराबर सिद्ध हुआ इसलिये 'तच्चापं मन्दफलं' यह आचार्योंक्त ठीक नहीं है, सिद्धान्तशेखर में 'दोः फलस्य च धनुः कलादिकं इत्यादि' श्रीपत्युक्ति तथा 'मृदुदोः फलस्य चापं बुधा मन्दफलं वदन्ति' यह भास्करोक्ति आचार्योंक्तानुरूप ही है,

$\frac{\text{शीघ्रभुजफल} \times \text{त्रि}}{\text{शीघ्रकर्ण}} = \text{शीघ्रफलज्या}$; इसका चाप शीघ्रफल होता है, 'दोः फलत्रिगुण-

योरभिधातात्' इत्यादि श्रीपत्युक्ति आचार्योंक्त 'तद्गुणिताद् व्यासार्धात्कर्णलब्धधनुः' के अनुरूप ही है इति ॥ १७ ॥

अत्र विशेषविचारः

यथा-यथा कर्णो वर्धते तथा-तथाऽन्त्यफलज्यापि वर्धिता भवतीति मन्यते ब्रह्मगुप्तः। अतोऽभीष्टकाले पारमार्थिको ग्रहः प्रतिवृत्ते ग्र स्थाने न वर्तते, किन्तु ग्र स्थाने तिष्ठति। अतो वास्तवान्त्यफलज्या = ग्रन। अतो भू स्थानात् भूग्र व्यासार्धेन यो गोल-स्तत्रैव प्रतिमण्डले ग्रहभ्रमणं भवतीति ब्रह्मगुप्त-मतं साध्विति स्थापयन्ति भास्कराचार्याः। तदर्थमेव मन्दश्रुतिर्द्राक्ष्रुतिवत्प्रसाध्येत्यादि-वक्ष्यमाणविधिना भूग्र कलाकर्णमानं साधितं भास्करेण इत्यनया कल्पनया भुजफलचापसमं मन्दफलं भवति। अपूर्वेयं कल्पना ब्रह्मगुप्तस्य।

भ्रमणकालः=का.

अतः केप्लर द्वितीयसिद्धान्तेन

$$\frac{का_१}{का} = \frac{\text{क्षेफ असग}}{\text{दीवृफ}}.$$

अत्र मध्यममानेनैकस्मिन् दिने मन्दकेन्द्रगतिमानं न प्रकल्प्य ततोऽनुपातः ।
यदि भगणभोगकालेन भगणभागा लभ्यन्ते तदैकदिनेन किम् ।

$$\text{जातमेकस्मिन् दिने मध्यकेन्द्रमानम्} = \frac{२\pi}{का} = न.$$

(अत्र π = रूपव्यासार्धोऽर्धपरिधिमानम्),

$$\therefore का = \frac{२\pi}{न}.$$

$$\therefore \frac{का_१ \cdot न}{२\pi} = \frac{\text{क्षेफ असग}}{\text{दीवृफ}}.$$

अत्र दीवृफ = $\pi \cdot अ \cdot क$.

$$\therefore \frac{का_१ \cdot न}{२\pi} = \frac{\text{क्षेफ असग}}{\pi \cdot अ \cdot क}.$$

$$\therefore का_१ \cdot न = \frac{२ \cdot \text{क्षेफ असग}}{अ \cdot क}.$$

अत्र का_१ समे काले का_१ · न इदं मन्दकेन्द्रमानं भवति । अतः मन्दकेन्द्रम् =

$$\frac{२ \text{क्षेफ असग}}{अ \cdot क} = म.$$

अथ दीर्घवृत्तसिद्धान्तेन—

$$\frac{\text{गल}}{\text{वल}} = \frac{\text{क}}{अ}.$$

$$\text{परं च } \frac{\text{गल}}{\text{वल}} = \frac{\text{फ अलग}}{\text{फ अलव}}.$$

$$\therefore \frac{\text{फ अलग}}{\text{फ अलव}} = \frac{\text{क}}{अ}.$$

$$\therefore \text{फ अलग} = \text{फ अलव} \cdot \frac{\text{क}}{अ}.$$

परं च फ अलव = $\triangle अकव + \triangle लकव$.

$$\therefore \text{फ अलग} = \frac{\text{क}}{अ} (\triangle अकव + \triangle लकव)$$

$$= \frac{क}{अ} \left(\frac{के \cdot अ^१}{२} + \frac{ज्याके \cdot अ \cdot लक}{२} \right)$$

$$= \frac{क \cdot अ}{२} \left(के_१ + \frac{ज्याके_१ \cdot लक}{अ} \right)$$

$$= \frac{क \cdot अ}{२} (के_१ + ज्याके_१ \cdot कोज्याके_१)$$

$$\text{एवं } \triangle \text{ सलग} = \frac{\text{सल} \cdot \text{गल}}{२}$$

$$= \frac{\text{सल} \cdot \text{वल} \cdot क}{२ \cdot अ}$$

$$= \frac{अ \cdot क}{२} \cdot \frac{\text{सल} \cdot \text{वल}}{अ \cdot अ}$$

$$= \frac{अ \cdot क}{२} \cdot \frac{(\text{लक} + \text{सक}) \cdot \text{वल}}{अ \cdot अ}$$

$$= \frac{अ \cdot क}{२} \cdot \frac{\text{लक} \cdot \text{वल}}{अ \cdot अ} + \frac{\text{सक} \cdot \text{वल}}{अ^२}$$

$$= \frac{अ \cdot क}{२} (\text{कोज्याके}_१ \cdot ज्याके_१ + इ - ज्याके_१)$$

अनयोरन्तरेण—

$$\triangle \text{ असग} = \frac{अ \cdot क}{२} (के_१ - इ \cdot ज्याके_१)$$

$$\therefore म = के_१ - इ \cdot ज्याके_१ \dots\dots\dots (१)$$

एतेन च्युतिकेन्द्रमुखेन मध्यमकेन्द्रमानं सिद्धयति अतः परं स्फुटकेन्द्रद्वारा तन्मानमन्विष्यते ।

अथ दीर्घवृत्तसिद्धान्तेन—

$$\text{मक} \cdot \text{कोज्याष} = अ \cdot \text{कोज्याके}_१ - इ \cdot अ$$

$$\text{एवं मक} \cdot \text{ज्याष} = क \cdot ज्याके_१$$

वर्गयोर्योगेन—

$$\text{मक}^२ \cdot \text{कोज्या}^२ ष = अ^२ \cdot \text{कोज्या}^२ के - २ अ \cdot \text{कोज्याके} \cdot इ \cdot अ + इ^२ \cdot अ^२$$

एवं मक^१ ज्या^२ष = क^२ ज्या^१के,

योगेन—

$$\text{मक}^1 = \text{अ}^1 \cdot \text{कोज्या}^1 \text{के}_1 - २ \text{ अ} \cdot \text{कोज्याके}_1 \cdot \text{इ} \cdot \text{अ} + \text{इ}^1 \cdot \text{अ}^1 + \text{ज्या}^1 \text{के}_1 \cdot \text{क}^2$$

$$= \text{अ}^1 \cdot \text{कोज्या}^1 \text{के}_1 - २ \text{ अ} \cdot \text{कोज्याके}_1 \cdot \text{इ} \cdot \text{अ} + \text{इ}^1 \cdot \text{अ}^2 + \text{अ}^1 (१ - \text{इ}^1) \cdot \text{ज्या}^1 \text{के}_1$$

$$= \text{अ}^1 \cdot \text{कोज्या}^1 \text{के}_1 - २ \text{ अ} \cdot \text{कोज्याके}_1 \cdot \text{इ} \cdot \text{अ} + \text{अ}^2 \cdot \text{इ}^1 + (१ - \text{इ}^2) \text{ ज्या}^1 \text{के}_1$$

$$= \text{अ}^1 (\text{कोज्या}^1 \text{के}_1 - २ \text{ कोज्याके}_1 \cdot \text{इ} + \text{इ}^2 - \text{इ}^2) \cdot \text{ज्या}^1 \text{के}_1 + \text{ज्या}^1 \text{के}_1$$

$$= \text{अ}^1 (\text{कोज्या}^1 \text{के}_1 + \text{ज्या}^1 \text{के}_1 - २ \text{ कोज्याके}_1 \cdot \text{इ} + \text{इ}^2 \cdot \text{कोज्या}^1 \text{के}_1)$$

$$= \text{अ}^1 (१ - \text{इ} \cdot \text{कोज्याके}_1)^2$$

मूलेन—

$$\text{मक} = \text{अ} (१ - \text{इ} \cdot \text{कोज्याके}_1) \dots \dots \dots (२)$$

अथ त्रिकोणगणितेन—

$$२ \text{ ज्या}^1 \frac{१}{२} \text{ ष} = १ - \text{कोज्याष}$$

$$\therefore २ \text{ मक} \cdot \text{ज्या}^2 \frac{१}{२} \text{ ष} = \text{मक} (१ - \text{कोज्याष})$$

$$= \text{मक} - \text{मक} \cdot \text{कोज्याष}$$

$$= \text{अ} (१ - \text{इ} \cdot \text{कोज्याके}_1) - (\text{अ} \cdot \text{कोज्याके}_1 \cdot \text{इ} \cdot \text{अ})$$

$$= \text{अ} (१ - \text{इ} \cdot \text{कोज्याके}_1) - (\text{अ} \cdot \text{कोज्याके}_1 \cdot \text{इ} \cdot \text{अ})$$

$$= \text{अ} १ - \text{इ} \cdot \text{कोज्याके}_1 - (\text{कोज्याके}_1 \cdot \text{इ})$$

$$= \text{अ} \{ १ - \text{इ} \cdot \text{कोज्याके}_1 - \text{कोज्याके}_1 + \text{इ} \}$$

$$\text{एवं } २ \text{ कोज्या}^1 \frac{१}{२} \text{ ष} \cdot \text{मक} = \text{मक} (१ + \text{कोज्याष})$$

$$= \text{अ} (१ - \text{इ} \cdot \text{कोज्याके}_1 + \text{कोज्याके}_1 - \text{इ})$$

$$\therefore \frac{\text{ज्या}^2 \frac{१}{२} \text{ ष}}{\text{कोज्या}^1 \frac{१}{२} \text{ ष}} = \frac{(१ - \text{इ} \cdot \text{कोज्याके}_1 - \text{कोज्याके}_1 + \text{इ})}{१ - \text{इ} \cdot \text{कोज्याके}_1 + \text{कोज्याके}_1 - \text{इ}}$$

$$= \frac{(१ + \text{इ}) (१ - \text{कोज्या के}_1)}{(१ - \text{इ}) (१ + \text{कोज्या के}_1)}$$

$$\therefore \text{स्प}^{\frac{1}{2}} \text{ष} = \frac{1+\text{इ}}{1-\text{इ}} \cdot \text{स्प}^{\frac{1}{2}} \text{के},$$

$$\therefore \text{स्प}^{\frac{1}{2}} \text{प} = \sqrt{\frac{1+\text{इ}}{1-\text{इ}}} \cdot \text{स्प}^{\frac{1}{2}} \text{के}, \dots \dots \dots (३)$$

एतेन च्युतिकेन्द्रमुखेन स्फुटकेन्द्रमानं सिद्धयति । पूर्वं तु (१) समीकरणे-
नापि च्युतिकेन्द्रमुखेन मध्यमकेन्द्रमानं सिद्धम् । अथेदानीं मध्यमस्फुटयोः सम्बन्धो
गदेपणीयः ।

अत्र यदि इ=ज्यास, ष=य, के=र,

$$\text{तर्हि } \frac{1+\text{इ}}{1-\text{इ}} = \frac{1+\text{ज्यास}}{1-\text{ज्यास}} = \frac{1+२ \text{ कोज्या}^{\frac{1}{2}}\text{स} \cdot \text{ज्या}^{\frac{1}{2}}\text{स}}{1-२ \text{ कोज्या}^{\frac{1}{2}}\text{स} \cdot \text{ज्या}^{\frac{1}{2}}\text{स}}$$

$$= \frac{\text{कोज्या}^{\frac{1}{2}}\text{स} + \text{ज्या}^{\frac{1}{2}}\text{स} + २ \text{ कोज्या}^{\frac{1}{2}}\text{स} \cdot \text{ज्या}^{\frac{1}{2}}\text{स}}{\text{कोज्या}^{\frac{1}{2}}\text{स} + \text{ज्या}^{\frac{1}{2}}\text{स} - २ \text{ कोज्या}^{\frac{1}{2}}\text{स} \cdot \text{ज्या}^{\frac{1}{2}}\text{स}}$$

$$= \frac{(\text{कोज्या}^{\frac{1}{2}}\text{स} + \text{ज्या}^{\frac{1}{2}}\text{स})^2}{(\text{कोज्या}^{\frac{1}{2}}\text{स} - \text{ज्या}^{\frac{1}{2}}\text{स})^2}$$

$$= \frac{(१+\text{स्प}^{\frac{1}{2}}\text{स})^2}{(१-\text{स्प}^{\frac{1}{2}}\text{स})^2} \therefore \sqrt{\frac{१+\text{इ}}{१-\text{इ}}} = \frac{१+\text{स्प}^{\frac{1}{2}}\text{स}}{१-\text{स्प}^{\frac{1}{2}}\text{स}}$$

$$\therefore \text{स्प}^{\frac{1}{2}} \text{ष} = \text{स्प}^{\frac{1}{2}} \text{के} \cdot \sqrt{\frac{१+\text{इ}}{१-\text{इ}}}$$

$$\therefore \text{स्प}^{\frac{1}{2}} \text{य} = \frac{१+\text{स्प}^{\frac{1}{2}}\text{स}}{१-\text{स्प}^{\frac{1}{2}}\text{स}} \cdot \text{स्प}^{\frac{1}{2}} \text{र}$$

अथ त्रिकोणमित्या—

$$\text{स्प}^{\frac{1}{2}} \text{ष} = \frac{\text{इ} \frac{\text{इय}}{२} + \text{इ} - \text{इय}/२}{\text{इ} \frac{\text{इय}}{२} - \text{इ} - \text{इय}/२}$$

$$\text{एवं स्प}^{\frac{1}{2}} \text{र} = \frac{\text{इ} \frac{\text{इर}}{२} + \text{इ} - \text{इर}/२}{\text{इ} \frac{\text{इर}}{२} - \text{इ} - \text{इर}/२}$$

योगान्तरनिष्पत्त्या—

$$\text{इ} \frac{\text{इय}}{२} = \text{इ} \frac{\text{इर}}{२} \cdot \frac{१+\text{इ} - \text{इर}^{\frac{1}{2}}}{१-\text{इ} - \text{इर}^{\frac{1}{2}}} \cdot \frac{\text{स्प}^{\frac{1}{2}} \text{स}}{\text{स्प}^{\frac{1}{2}} \text{स}}$$

पक्षयोर्लघुरिक्थेन—

$$य = र + २ \left(\text{स्प } \frac{१}{३} \text{ स} \cdot \text{ज्या } र + \frac{१}{३} \text{ स्प}^२ \frac{१}{३} \text{ स ज्या } २ र + \dots \right)$$

$$\text{एवमेव } इ = \text{ज्यास} ।$$

$$\therefore \text{स्प } \frac{१}{३} \text{ स} = \frac{\sqrt{१ - इ^२}}{इ}$$

$$= \frac{इ}{२} + \frac{इ^३}{८} + \dots$$

अत उत्थापनेन—

$$य = र + \left(इ + \frac{इ^३}{८} \right) \text{ज्या } र + \frac{इ^२}{४} \text{ज्या } २ र + \dots$$

$$\text{वा } ष = के_२ + \left(इ + \frac{इ^३}{८} \right) \text{ज्याके}_१ + \frac{इ^२}{४} \text{ज्या } २ के_१ + \dots$$

अत्र (१) समीकरणेन—

$$म = के_१ - इ ज्याके_१$$

यद्यत्र प्रथमवारं दक्षिणपक्षस्य खण्डं त्यज्यते तदा म = के, तत उत्थापनेन—

$$के_१ = म + इ \cdot ज्याम \cdot$$

अनेन (४) समीकरणमुत्थाप्य जातम्

$$ष = म + इ \cdot ज्याम + \left(इ + \frac{इ^३}{८} \right) ज्या (म + इ \cdot ज्याम)$$

$$= म + इ \cdot ज्याम + इ \cdot ज्या (म + इ \cdot ज्याम) + \dots$$

$$= म + २ इ \cdot ज्याम + \dots$$

$$\therefore ष - म = २ इ \cdot ज्याम \text{ अन्यपदत्यागात् ।}$$

अत्र म मध्यमकेन्द्रं, ष स्फुटकेन्द्रं, मध्यस्फुटकेन्द्रान्तरं मन्दफलं भवत्यतः

मन्दफलम् = २ इ ज्याम यद्यत्र २ इ = अन्त्यफलज्या, तथा त्रि = १, तदा ब्रह्मगुप्तोक्तं मृदुदोः फलचारूपं मन्दफलं नवीनमतेनापि सिद्धम् । अत्रान्त्यफलज्या = २ इ एतदर्थमन्यः प्रकारो द्रष्टव्यः तत्त्वग्रे वक्ष्ये ।

अत्रैव केचन नवीनास्तु अन्यथैव क्षेत्रभङ्गीं प्रदर्श्य चन्द्रार्कयोर्मन्दफलं
प्रसाध्य प्राचीनमतं समर्थयन्ति ।

तद्यथा

$$\frac{१३ इ^१}{१२} . ज्या ३ म + \dots\dots\dots$$

अतोऽत्र गोउफउमहाशयेन $\frac{P}{अ} = २ इ - \frac{इ^१}{४}$ प्रकल्पितम्, तत्र इ अस्य

अत्यल्पत्वात् $\frac{इ^१}{४}$ त्यज्यते तदा $\frac{P}{अ} = २ इ$.

$$\therefore E = २ इ . ज्याम = \frac{P}{अ} . ज्याम .$$

अतोऽत्रापि ब्रह्मगुप्तमतेन—

$$मन्दफज्या = \frac{ज्याअ . ज्याम}{अ}$$

$$अथवा = २ इ . ज्याम ., त्रि = १$$

$$२ इ = ज्यापरमफलम् ।$$

इदानीं रविचन्द्रयोः स्फुटत्वार्थमाह

देशान्तरे खमध्ये भुजफलचापे भुजान्तरे च कृते ।

उन्मण्डलेऽर्कचन्द्रौ स्पष्टौ रविचरदले क्षितिजे ॥ १८ ॥

वा. भा.—इदानीं वा देशान्तरादिभिः संस्कारैः स्वदेशे यादृशौ रविचन्द्रौ भवतः यत्र प्रदेशे तत्प्रतिपादनायार्थमाह । लङ्काकोदयकालिकौ यौ रविचन्द्रौ मध्यौ तौ देशान्तरे कृते कर्मणि स्वदेशे मध्यौ भवतः यस्माल्लंकासमयाम्योत्तररेखातः प्राक् पश्चाद्वा स्वदेशेनैव भवितव्यम् । तत्र च प्रथमं पश्चाद्वाकोदयो भवति । रेखाकोदयादित्यत उपपन्नं भुजफलचापे भुजान्तरे च कृते, उन्मण्डलकेऽर्कचन्द्राविति भुजफलचापे स्वफलचापे स्वफले कृतेरपि स्फुटौ भवतः यस्मात् प्रतिमण्डलस्थौ स्वफलेनोपचितावपचितौ च कक्षामण्डले दृग्गतौ भवतः स्पष्टावपि तावेवामिधीयेते । किन्तून्मण्डलसन्निधौ भवतः यस्मान्मध्यमरवेरुदयकालिकः सावनोऽहर्गणस्तस्माद्भुजान्तरे कृते उन्मण्डले स्पष्टौ भवतः यतो मध्यस्फुटरव्युदययोरन्तराद् भुजान्तरोत्पत्तिरुन्मण्डलञ्च निरक्षदेशक्षितिजमुच्यते । तस्मादुपपन्नम् ।

रविचरदले क्षितिज इतिस्वसम्बन्धी यच्चरार्धं तस्मिन् कृते सति क्षितिजस्थे रवौ रविचन्द्रौ स्पष्टौ भवतः । यस्मात्स्वदेशे क्षितिजोन्मण्डलयोरन्तरं यच्चरदलं स्वाहोरात्रार्धवृत्ते तस्मादेतदप्युपपन्नम् । सर्वं गोले प्रदर्शयेत् । अत्रार्धा-
आर्या रविचन्द्रयोर्ग्रहणग्रहोपलक्षणार्था । तेनान्येऽपि ग्रहाः देशान्तरे कृते स्वदेशे भवन्ति, मन्दशीघ्रभुजफलचापद्वये भुजान्तरे च कृते उन्मण्डले

स्पष्टा भवन्ति । रविचरदले च यथासंभवं कृतेऽर्कोदयकालिका भवन्ति । यद्यर्कसावनेनानीताः अथान्यग्रहमधुनाहर्गणेनानीतास्तदा तत्सर्वं हि चरदले कृते तस्यैव ग्रहस्योदयकालिका भवन्तीति रव्यादयोऽथनक्षत्रसावनेनानीतास्ते चरदलं विना चोनाधिका भवन्तीति यदुक्तं रविचरदले कृते क्षितिजे रविचन्द्रौ भवतस्तल्लंकार्कोदयास्तमयिकावेव देशान्तरकृती नान्यावित्यत आर्यार्द्धिनाह ॥१८॥

वि. भा.—खमध्ये (खस्वस्तिके) ऽर्थात्स्फुटदिनार्धकाले यद्यर्कचन्द्रौ स्पष्टावपेक्षितौ तदा मध्यमरवी चन्द्रे च भुजफलचापे (मन्दफले), भुजान्तरे च कृतेऽर्थात्संस्कृते सत्युन्मण्डले तौ स्फुटौ भवतः, तत्र रविचरदले (रविचरार्धे) संस्कृते सति क्षितिजे (स्वक्षितिजे) स्फुटौ रविचन्द्रौ भवेतामिति ॥१८॥

अत्रोपपत्तिः

यतो लङ्का याम्योत्तररेखातः पूर्वं पश्चाद्वा स्वदेशोऽतो देशान्तरसंस्कृतौ लङ्कार्कोदयकालिकौ रविचन्द्रौ स्वदेशमध्यमौ भवेताम् तत्र रेखाकोदयार्धप्रथमं पश्चाद्वा रव्युदयो भवति, तथा मन्दफलभुजान्तरयोः संस्करणेन स्वनिरक्षक्षितिजे रविचन्द्रौ स्फुटौ भवतस्तत्र रविचरार्धफलसंस्करणेन स्वक्षितिजे तौ स्फुटौ भवेतामिति । सिद्धान्तशेखरे श्रीपतिना 'अध्वकर्मणि कृते स्वमध्यमौ दोः फले रविफले इत्यादिना' ऽऽचार्योक्तानुरूपमेव रविचन्द्रयोः स्पष्टीकरणं प्रदर्शितमस्ति, भास्करतः प्राचीना आचार्याः स्वदेशोदयकालिकग्रहज्ञानार्थं पूर्वप्रतिपादितानि देशान्तरादित्रयीष्वेव कर्मणि कृतवन्तः, भास्करेणैकमपूर्वमुदयान्तरसंज्ञकं कर्म प्रतिपाद्य 'लङ्कायां भास्करोदये मध्याः' इति ब्रह्मगुप्तोक्तं तिरस्कृत्य 'यतोऽन्तरं तच्चलमल्पकं चे' त्यादिना पुनः समाधानं कृतमिति ॥ १८ ॥

अब रवि और चन्द्र के स्फुटत्व के लिये कहते हैं

हि. भा.—स्फुटदिनार्धकाल में यदि स्पष्टरवि और स्पष्ट चन्द्र अपेक्षित हों तो मध्यमरवि में और मध्यमचन्द्र में मन्दफल, भुजान्तर और देशान्तर इन तीनों कर्मों के संस्कार करने से उन्मण्डल में अर्थात् स्वनिरक्षक्षितिज में वे दोनों (रवि और चन्द्र) स्पष्ट होते हैं उनमें रविचरार्धफल संस्कार करने से स्वक्षितिज में स्पष्टरवि और स्पष्ट चन्द्र होते हैं इति ॥ १८ ॥

उपपत्ति

लङ्का याम्योत्तररेखा से स्वदेश पूर्व वा पश्चिम में है इसलिये लङ्कार्कोदयकालिक रवि और चन्द्र में देशान्तर संस्कार करने से स्वदेश में वे दोनों होते हैं, वहाँ रेखाकोदय से पहले या पीछे रवि का मन्दफल होता है, मन्दफल और भुजान्तर का संस्कार करने से स्वनिरक्षक्षितिज में स्पष्टरवि और स्पष्टचन्द्र होते हैं, उनमें रविचरार्ध का संस्कार करने से

स्वक्षितिज में स्पष्टरवि और स्पष्टचन्द्र होते हैं, सिद्धान्तशेखर में श्रीपति ने 'अध्वकर्मणि कृते स्वमध्यमो' इत्यादि से आचार्योक्तानुरूप ही रवि और चन्द्र का स्पष्टीकरण किया है। भास्कराचार्य से प्राचीन आचार्यों ने स्वदेशोदयकालिक ग्रहज्ञान के लिये पूर्व प्रतिपादित देशान्तर आदि तीन ही कर्म किये हैं, भास्कराचार्य ने एक अपूर्व उदयान्तर संज्ञक कर्म कह कर 'लङ्कायां भास्करोदये मध्याः' इस ब्रह्मगुप्त कथन का अनादर कर 'यतोऽन्तरं तच्चलमल्पकं च' इससे पुनः उनके मत का समाधान किया है इति ॥१८॥

इदानीमार्यभटोक्तं स्फुटीकरणं न युक्तमित्याह

अर्कोदयास्तमययोर्विना चरार्धेन रात्रिदिनदलयोः ।

न स्फुटमार्यभटोक्तं स्पष्टीकरणं स्फुटोक्तिरतः ॥ १९ ॥

वा. भा.—लङ्काकोदयकालिको स्पष्टो देशान्तरफलसंस्कृतौ चरदलेन यदा संस्क्रियेते तदा स्वदेशे प्राक् क्षितिजस्थे रवौ तात्कालिको भवतः । अथास्तमयिकौ यथोक्तौ तदपि रविचरदलकर्मणि कृते परक्षितिजस्थे रवौ तात्कालिको भवतः, सर्व ग्रहाणां योज्यम् । विना चरार्धेन रात्रिदिनदलयोः यस्माद्याम्योत्तरमण्डलं चरदल-वशान्न भिद्यते महत्याप्यक्षोन्नत्या सर्वमेतत् गोले प्रदर्शयेत् । इष्टकालिकास्तु ग्रहाश्चरदलकर्म विनापि स्फुटा भवन्तीति यस्मात् स्वदेशार्कोदयादस्त-मयाद्वा स कालः कलित इति, आर्यभटोक्तं स्पष्टीकरणं स्फुटोक्तिरतः स्पष्टार्थ-मिदमार्याध्वम् ।

वि. भा.—चरसंस्कारेण विनाऽर्धरात्रे दिनार्धे च रविचन्द्रौ स्फुटौ भवतः, आर्यभटकथितं स्पष्टीकरणं न स्फुटमतोऽस्मात्कारणात्स्फुटीकरणकथनं युक्तम-स्तीत्याचार्येण स्वकीयस्पष्टीकरणकथने कारणं प्रतिपाद्यते ॥१९॥

अत्रोपपत्तिः

स्वदेशनिरक्षदेशयोर्दिनार्धं रात्र्यर्धं चैककालावच्छेदेनैव भवत्यतस्तत्र चरार्ध-संस्कारस्यावश्यकता न भवतीति ॥१९॥

अब आर्यभटोक्त स्फुटीकरण ठीक नहीं है इसको कहते हैं

हि. भा.—चर संस्कार के विना अर्धरात्रि में और दिनार्ध में रवि और चन्द्र स्फुट होते हैं, आर्यभट का कहा हुआ स्पष्टीकरण स्फुट नहीं है । स्पष्टीकरण का कहना ठीक है इससे आचार्य अपने स्पष्टीकरण कथन में कारण कहते हैं, इति ॥१९॥

उपपत्ति

स्वदेश में और निरक्ष देश में दिनार्ध और रात्र्यर्ध एक ही समय में होता है

इसलिये वहाँ चरार्ध संस्कार का अभाव होता है अर्थात् चरार्ध संस्कार की आवश्यकता नहीं होती है इति ॥१६॥

इदानीं रविचन्द्रयोः स्पष्टीकरणार्थं मन्दपरिध्यंशानाह

चार्येणाप्येतदनुकरणमेव कृतमिति ॥२०-२१॥

अब रवि और चन्द्र के स्पष्टीकरण के लिए मन्द परिधियों को कहते हैं

हि. भा.—चौदह अंश में दो स्थानों में एक अंश के तृतीयांश (बीसकला) को घटाने से सूर्य के ऋणमन्दफल में वा धनमन्दफल में मध्याह्न काल में मन्द परिध्यांश होता है, ऋणमन्दफल में वा धनमन्दफल में दिनार्ध से पूर्वकपाल में पञ्चदश १५ घटी कर के नत सूर्य के मध्याह्न मन्दपरिधिमान में क्रम से एक अंश के तृतीयांश (२० कला) को युग और हीन करना चाहिए, दिनार्ध से पश्चिम कपाल में ऋणमन्दफल में और धनमन्दफल में मध्याह्न परिधिमान में बीसकला को क्रम से हीन और युत करना तब पूर्व और पश्चिम उन्मण्डलस्थ सूर्य का मन्द परिध्यांश होता है। चन्द्र के ऋण या धन मन्दफल रहने पर बत्तीस ३२ में दो स्थानों में चौबीस २४ कला को घटा देना तब मध्याह्न में उनके मन्द परिध्यांश होते हैं। सूर्य ही की तरह पूर्वकपाल में और पश्चिमकपाल में पञ्चदश १५ घटी करके नत चन्द्र के ऋणमन्दफल में मध्याह्न परिधिमान में बावन ५२ कला घटा देना, धनमन्दफल में पञ्चदश घटी करके नतचन्द्र के मध्याह्न परिधिमान में ५२ कला को क्रम से युत और हीन करना तब पूर्व और पश्चात् उन्मण्डलस्थ चन्द्र के मन्द परिध्यांश होता है। यथा.

रवि के ऋण मन्दफल में

धन मन्दफल में

मध्याह्न में मन्द परिधि = १३° १४०'

मध्याह्न में मन्दपरिधि = १३° १४०'

प्राक् उन्मण्डलस्थ सूर्य में = १४° १०'

प्राक् उन्मण्डलस्थ सूर्य में = १३° १२०'

पश्चात् उन्मण्डलस्थ सूर्य में = १३° १२०'

पश्चात् उन्मण्डलस्थ सूर्य में = १४° १०'

चन्द्र के ऋण मन्दफल में

धन मन्दफल में

मध्याह्नमन्दपरिधि = ३१° १३६'

मध्याह्नमन्दपरिधि = ३१° १३६'

प्राक् उन्मण्डलस्थ चन्द्र में = ३०° १४४'

प्राक् उन्मण्डलस्थ चन्द्र में = ३०° १४४'

पश्चात् उन्मण्डलस्थ चन्द्र में = ३२° १२८'

पश्चात् उन्मण्डलस्थ चन्द्र में = ३०° १४४'

आर्यभट के मत से रवि की मन्द परिधि = १३° १३०', चन्द्र की मन्द परिधि = ३१° १३०' ब्रह्मगुप्त पठित परिधिमान को और आर्यभट पठित परिधिमान को देखने से दोनों में कुछ अन्तर पड़ता है, सूर्यसिद्धान्त में—

'रवेर्मन्दपरिध्यांशान्नवः क्षीतगो रदाः युग्मान्ते । विषमान्ते च नखलिप्तोन्तितस्तयोः'

इस तरह है, भिन्न-भिन्न परिध्यंश देखने से मालूम होता है कि ग्रहों की मन्दान्त्य फलज्यायें सदा स्थिर नहीं हैं क्योंकि मध्यम ग्रह को केन्द्र मान कर मन्दान्त्य फलज्या व्यासार्ध से जो वृत्त बनता है वह मन्दनीचोच्चवृत्त परिधि है, जिन जिन आचार्य को जितनी-जितनी मन्दान्त्य फलज्या उपलब्ध हुई उसी के अनुसार मन्द परिधिमान अपने-अपने सिद्धान्त में भिन्न-भिन्न लिखे हैं इति ॥२०-२१॥

उपपत्ति

इसके विषय में चतुर्वेदाचार्य ने 'इस में उपलब्धि ही उपपत्ति है, कहा है' भास्कराचार्य ने भी इन्हीं का अनुकरण किया है इति ॥२०-२१॥

इदानीमिष्टे नते स्फुटपरिध्यानयनमाह

तद्द्युदलपरिध्यन्तरगुणा हृता त्रिज्यया च नतजीवा ।

अने धनमृणमधिके दिनार्धपरिधौ स्फुटः परिधिः ॥ २२ ॥

अत्रोपपत्तिः

ये किल पूर्व मन्दनीचोच्चवृत्तपरिधयः पठितान्ते दिनार्धकाल एव, ऋणे घने च फले प्राक्पश्चिमोन्मण्डलस्थे रवौ चन्द्रे च ये परिधयस्तयोः (रविचन्द्रयोः), स्वस्वदिनार्धपठितपरिधिना सहैतत्परिधेर्यन्तरं तद्वशादनुपाते-‘यदि त्रिज्यातुल्यया नतकालज्ययेदं परिध्यन्तरं लभ्यते तदेष्टनतकालज्यया किमिति’ नानेनेष्टपरिध्यन्तरं समागच्छति, पठितपरिधा- (दिनार्धपरिधौ) वेतद्वृणं धनं कार्यं तदेष्टस्थानीयः स्फुटः परिधिर्भवेदेवेति, सिद्धान्तशेखरे श्रीपतिना ‘तदिनार्धपरिधिद्वयान्तरेणाहता स्वनतशिञ्जिनीहृता । त्रिज्ययाऽथपरिधौ दिनार्धजे हीनके स्वमधिके त्वृणं स्फुटम्’ ज्ञेनाऽऽचार्योक्तानुरूपमेव कथितमिति ॥ २२ ॥

अब इष्टनतकाल में स्फुट परिध्यानयन को कहते हैं

हि. भा.—इष्टनतज्या को प्राक् पश्चिम उन्मण्डल में रवि और चन्द्र के रहने से जो परिधि पहले कही गयी है पठित परिधि (दिनार्ध परिधि) के साथ उसका जो अन्तर है उससे गुणा कर त्रिज्या से भाग देकर जो फल हो उसको दिनार्ध परिधि में ऋण वा धन करना (जिस परिधि के साथ दिनार्ध परिधि का अन्तर करते हैं उस परिधि से दिनार्ध परिधि ऊन हो तब दिनार्ध परिधि में जोड़ना, दिनार्ध परिधि के अधिक रहने से दिनार्ध परिधि में पूर्वागत फल को ऋण करना) तब इष्टस्थानीय स्फुट परिधि होती है इति ॥ २२ ॥

उपपत्ति

पहले जो मन्दनीचोच्चवृत्त परिधि पठित है वह दिनार्ध काल ही में, ऋण फल में और घन फल में प्राक् उन्मण्डल में और पश्चिमोन्मण्डल में रवि और चन्द्र के रहने से जो परिधि होती है उसको दिनार्ध पठित परिधि के साथ जो अन्तर होता है उसके वश से ‘यदि त्रिज्यातुल्य नतकालज्या में यह परिध्यन्तर पाते हैं तो इष्टनतकालज्या में क्या’ इस अनुपात से इष्टपरिध्यन्तर आता है, दिनार्ध परिधि (पठित परिधि) में इसको ऋण और धन करने से इष्टस्थानीय स्फुट परिधि होती है, सिद्धान्तशेखर में ‘तदिनार्धपरिधिद्वयान्तरेणाहता’ इत्यादि संस्कृतोपपत्ति में लिखित श्लोक से श्रीपति ने प्राचार्योक्तानुरूप ही कहा है इति ॥ २२ ॥

इदानीं मन्दफलस्य धनत्वमूलात्त्वञ्चाह

भुजफलचापं केन्द्रे षड्राश्यूने रवावृणं मध्ये ।

स्वभुजफलचापमेवं षड्राश्यधिके घनं भवति ॥ २३ ॥

वा. भा.—इदानीं स्वमन्दोच्चनीचस्फुटपरिधिना आगतस्य फलस्य धनप्रदशंयन्नाह । मध्ये रवौ स्वकर्माद्भवं भुजफलचापं प्रागेव प्रदर्शितम् । अतद्वृणं भवति, षट् राश्यूने स्वमन्दकेन्द्रे यस्मात् प्रथमकेन्द्रपदे फलमूलात्

भवति । ततो द्वितीयपदोत्क्रमधनफलेनापचीयमानक्षयं यावत् । यावत्तावदर्धचक्र-
मत उक्तं षट्पराक्षयने केन्द्रे स्वमृणमिति । अधिके तु पुनः केन्द्रेऽर्धचक्रवत् फलं
घनं भवतीत्यनुक्तमपि ज्ञायते । ततस्तृतीयपदफलं घनम् । तच्चतुर्थपदोत्क्रमक्षयफले-
नापचीयमानमपि चक्रं यावदतिरिच्यते । चन्द्रस्य तु पुनः षट्पराक्षयधिके
केन्द्रे घनं भवति, वा तदूनं क्षयः स्वभुजफलचापं रविवासनयैव विस्तरेण पूर्वमेव
क्षयधनोपपत्तौ प्रदर्शितेति, रविचन्द्रवन्नार्येयं ग्रहोपलक्षणार्था तेनान्येषामपि
ग्रहाणां मन्दकर्मैव योज्यमिति ।

वि. भा.—मन्दकेन्द्रे राशिषट्काल्पे भुजफलचापं (मन्दफलं) मध्ये रवावृणं
भवति, एवं राशिषट्काधिके मन्दकेन्द्रे स्वभुजफलचापं (रविमन्दफलं) मध्ये
रवौ घनं भवतीति ॥२३॥

अत्रोपपत्तिः

रविमन्दोच्चस्थानाग्नीचपर्यन्तं स्थिते मध्यमरवौ तन्मन्दकेन्द्रस्य (रविमन्दो-
च्चमध्यमरवेरन्तररूपस्य) मेषादिराशिषट्कान्तर्गतत्वान्मन्दफलेन (मध्यम-
स्पष्टरव्योरन्तरेण) हीनो मध्यमरविः स्पष्टरविर्भवेत् । नीचादुच्चपर्यन्तं स्थिते
मध्यमरवौ तत्केन्द्रस्य तुलादिराशिषट्कान्तरे विद्यमानत्वान्मन्दफलेन युक्तो मध्यम-
रविः स्फुटरविर्भवत्यतः सिद्धं यन्मेषादिकेन्द्रे मन्दफलमृणं तुलादिकेन्द्रे च मन्दफलं
घनं भवत्यतः श्लोके षड्पराक्षयने केन्द्रे (मेषादिकेन्द्रे) षड्पराक्षयधिके केन्द्रे (तुलादि-
केन्द्रे) व्याख्येयः, सिद्धान्तशिरोमणौ भास्करेण 'तुलाजादिकेन्द्रेफलं स्वर्णमेवं-
मृदुज्ञेयमिति' आचार्योक्तानुरूपमेव कथ्यत इति ॥२३॥

अब मन्दफल के घनत्व और ऋणत्व को कहते हैं

हि. भा.—छः राशि से अल्प मन्द केन्द्र (अर्थात् मेषादि केन्द्र) में मन्दफल को
मध्यमरवि में घटा देने से स्पष्ट रवि होते हैं। इसी तरह छः राशि से अधिक मन्द केन्द्र
(अर्थात् तुलादि केन्द्र) में मध्यमरवि में मन्दफल को जोड़ने से स्पष्टरवि होते हैं
इति ॥ २३ ॥

उपपत्ति .

मन्दोच्च स्थान से नीच पर्यन्त मध्यमरवि के रहने से रवि मन्दकेन्द्र (मन्दोच्च
और मध्यमरवि के अन्तर) के मेषादि छः राशि के अन्तर्गत होने के कारण रविमन्द-
फल को मध्यमरवि में घटाने से स्पष्टरवि होते हैं। नीच से उच्च पर्यन्त मध्यमरवि
के रहने से रविमन्द केन्द्र के तुलादि छः राशि के अन्तर्गत होने के कारण रविमन्द फल
को मध्यमरवि में जोड़ने से स्पष्टरवि होते हैं इससे सिद्ध होता है कि मेषादि केन्द्र में
मन्दफल ऋण होता है और तुलादि केन्द्र में मन्दफल घन होता है, सिद्धान्तशिरोमणि में

भास्कराचार्य भी 'तुलाजादिकेन्द्रे फलं स्वर्णमेवं मृदुज्ञेयं' इमसे आचार्योक्तानुरूप ही कहते हैं इति ॥ २३ ॥

इदानीं रविचन्द्रयोः स्पष्टीकरणे विशेषमाह

तिथ्यन्तदण्डमितिरत्र भवेत्स्फुटा सा,

प्राक् चेद्विधोर्धनफलाल्पमथात्र सौरम् ॥

तर्हि ध्रुवात् सनतकोटिगुणादिहान्यः,

साध्यो विदा गणितगोलविदा मुदैव ।

श्री ब्रह्मगुप्तनतकर्म भवेत् सुसूक्ष्ममेवं,

सकृत् सकलसम्बन्धरञ्जनार्थम् ॥

उदयान्तरभुजान्तरादिसंस्करणेन यो हि स्पष्टग्रहः समागच्छति वस्तुतो नहि स्पष्टग्रह इति ब्रह्मगुप्तोक्तमतकर्म पादानेन तत्साधनकर्तृभस्कराचार्यस्य श्रेष्ठ-

दपि ज्ञायते, सर्वे आकाशस्था ग्रहादयो भूवायुगोले परिणता अस्माकं प्रत्यक्षीभूताः स्पष्टा भवन्ति, तेन स्पष्टीकरणेन ये स्पष्टग्रहाः समागच्छन्ति तेषु यावता संस्कारेण भूवायुगोलपरिणताः स्पष्टग्रहा भवेयुस्तस्यैव नाम नतकर्म; ब्रह्मगुप्तः प्राचीनाः सूर्यसिद्धान्तकाराऽऽर्यभटप्रभृतिभिरेतत्सम्बन्धे स्वस्वसिद्धान्तेन किमपि लिखितवन्तः। मन्मते नतकर्मसंस्कारस्यातीवाऽऽवश्यकता प्रतीयते, विषयेऽस्मिन् सारासार-विचारदक्षा ज्योतिषिका भृशं विचारयन्तिवति ॥२४॥

अब रवि और चन्द्र के स्पष्टीकरण के सम्बन्ध में विशेष कहते हैं।

हि. ३७.—रवि और चन्द्र का दिनार्ध परिधियों से देशान्तरादि द्वारा स्फुटीकरण कर के उन स्पष्टरवि और स्पष्टचन्द्र से ग्रहण में तिथ्यन्त साधन करना, उस तिथ्यन्त कालिक रवि और चन्द्र के स्पष्ट परिधियों से स्पष्ट रवि और स्पष्ट चन्द्र साधन करना, उन स्पष्ट रवि और स्पष्ट चन्द्र से पुनः तिथ्यन्त साधन करना, पुनः स्पष्ट परिधियों से स्पष्टरवि और स्पष्ट चन्द्र साधन करना, इस तरह बार-बार करने से ग्रहण के लिये उपयुक्त स्पष्ट रवि और स्पष्ट चन्द्र होते हैं, प्राचार्य जी के इस अभिप्राय का भास्कराचार्य ने विशदरूप से प्रतिपादन किया है इसीलिये सिद्धान्त शिरोमणि में 'मुहुः स्फुटाऽतो ग्रहणो रवीन्द्रोस्तिथिस्त्विदं जिष्णुसुतो जगाद' भास्कराचार्य कहते हैं ॥२४॥

उपपत्ति

प्राचार्योक्त नतकर्म सकृत्प्रकार से भी हो सकता है जैसे गणितागत तिथ्यन्त काल और असकृत्प्रकार से साधित नत कर्म संस्कृत रवि और चन्द्र से उत्पन्न तिथ्यन्त काल के अन्तर घट्यात्मक मान मानते हैं (य) एतत्सम्बन्धि अंश = ६ य, गणितागत तिथ्यन्त काल में रवि के नत कालांश = न, इन दोनों के संस्कार करने से वास्तवगतकालांश = $n \pm 6y$, तब अनुपात करते हैं, यदि साठ घटी में रवि और चन्द्र की गत्यन्तर कला पाते हैं तो (य) घटी में क्या इस से ५ घटी में रवि और चन्द्र की अन्तर कला आती है,

$$\frac{य (चंगक—रगक)}{६०} = य \times ग, \text{ यहाँ } \frac{चंगक—रगक}{६०} = ग. \quad | \quad \text{'तिथ्यन्तनाडीनतबाहुमीर्व्या'}$$

$$\text{इत्यादि' भास्करोक्तप्रकार से सूर्य के नतकर्म} = \frac{रफ \times ज्या (n \pm 6y)}{४६२०} = रफ, \times ज्या$$

$$(n \pm 6y), \text{ यहाँ } \frac{रफ}{४६२०} = रफ, \text{ तथा चन्द्र के नतकर्म} = \frac{चंफ \times ज्या (n \pm 6y)}{४३७५}$$

$$= चंफ, \times ज्या (n \pm 6y), \text{ यहाँ } \frac{चंफ}{४३७५} = चंफ, \text{ इन दोनों का संस्कार पूर्व साधित अन्तर}$$

के बराबर होता है अन्यथा गणितागत रवि और चन्द्र के अन्तर और नतकर्म संस्कृत रवि और चन्द्र के अन्तर ५ घटयन्तर् में कैसे समान अन्तर को बनायेगा, अतः $ग \times य चंफ, \times ज्या$

$$(n \pm ६५) - रफ \times ज्या (n \pm ६५) = (चंफ, - रफ,) \times ज्या (n \pm ६५) इसलिये \frac{ग}{चंफ, - रफ,}$$

$$= \frac{ज्या (n \pm ६५)}{य} = पर = प, तब अनुपात करते हैं यदि दश अंश की ज्या = २१ पाते$$

$$हैं तो '६ य' एतत्तुल्य अंश की क्या भा गयी '६य' इसकी ज्या, ज्या ६य = \frac{२१ \times ६य}{१०},$$

$$इसी तरह \frac{२१ \times ३य}{१०} = ज्या ३य = \sqrt{\frac{त्रि \times उज्या ६य}{२}} = \sqrt{६० \times उज्या ६य} इसके$$

$$विलोम से \frac{२१^२ \times ३^२ \times य^२}{१०^२ \times ६०} = उज्या ६य ; चापयोरिष्टयोरित्यादि से ज्या (n \pm ६५)$$

$$= \frac{ज्यान \times कोज्या ६य}{त्रि} \pm \frac{कोज्यान \times ज्या ६य}{त्रि} = ज्यान - \frac{ज्यान \times उज्या ६य}{त्रि}$$

$$\pm \frac{कोज्यान \times ज्या ६य}{त्रि} = ज्यान - \frac{ज्यान \times २१^२ \times ३^२ \times य^२}{१०^२ \times ६० \times १२०} \pm \frac{कोज्यान \times २१ \times ६य}{१० \times १२०}$$

$$= ज्यान - \frac{ज्यान \times य^२}{\left(\frac{२००}{२१}\right)^२ \times २} \pm \frac{कोज्यान \times य}{\frac{२००}{२१}} = ज्यान - \frac{ज्यान \times य^२}{२ हा} \pm \frac{कोज्यान \times य}{हा},$$

$$\frac{ज्या (n \pm ६५)}{य} = पर = प = \frac{ज्यान}{य} - \frac{ज्यान \times य}{२ हा} \pm \frac{कोज्यान}{हा} दोनों पक्षों को हा गुणने से$$

$$प \times हा = ध्रुव = ध्रु = \frac{ज्यान \times हा}{य} - \frac{ज्यान \times य}{२ हा} \pm कोज्यान दोनों पक्षों में समशोषन$$

$$करने से तथा ज्यान से भाग देने से \frac{ध्रु \pm कोज्यान}{ज्यान} = \frac{हा}{य} - \frac{य}{२ हा} छेदगम से २ हा^२ - य^२$$

$$= \pm य \times हा \times य \times २। यहां \frac{ध्रु \pm कोज्यान}{ज्यान} = ध्रुत्व = \pm य समशोषन करने से य^२ \pm २ य \times$$

$$हा \times य = २ हा^२ वर्ग पूर्ति करने से य^२ \pm २ य \times हा \times य + य^२ \times हा^२ = २ हा^२ + य^२ \times हा^२ \\ = हा^२ (य^२ + २) मूल लेने से य \pm य \times हा = हा \sqrt{य^२ + २} \therefore य = हा \\ (\sqrt{य^२ + २} \mp य)$$

इससे म. म. सुधाकर द्विवेदी जी के सूत्र उपपन्न होते हैं जो कि संस्कृतोपपत्ति में लिखे हुये हैं। उदयान्तर भुजान्तरादि संस्कार से जो स्पष्टग्रह होते हैं वे वस्तुतः स्पष्टग्रह नहीं होते हैं यह विषय ब्रह्मसुप्त के नतकर्म कहने से तथा नतकर्म साधन-

कारक भास्कराचार्य के लेख से मालूम होता है, आकाशस्थ ग्रहादि भूवायु गोल में परिणत होकर हम लोगों को प्रत्यक्षीभूत (स्पष्ट) होते हैं, इसलिये स्पष्टीकरण से जो स्पष्टग्रह आते हैं उनमें जितना संस्कार करने से भूवायु गोल परिणत स्पष्टग्रह हो उसी को नतकर्म कहना उचित है, ब्रह्मगुप्त से प्राचीन सूर्यसिद्धान्तकार, आर्यभट्ट प्रभृति ने इसके विषय में अपने-अपने सिद्धान्त में कुछ नहीं लिखा है। मेरे मत में नतकर्म संस्कार की अतीव आवश्यकता है, इस विषय के उपर विज्ञ ज्योतिषिक लोग विचार करें इति ॥ २४ ॥

इदानीं ग्रहणे सूर्याच्चन्द्रमसोनंतकालमाह

अब ग्रहण में सूर्य और चन्द्र के नतकाल को कहते हैं

हि. भा.—चन्द्रग्रहण में पूर्णान्तकाल में मध्याह्नकाल से पहले या पीछे जितनी
घटी में रवि नत होता है वह सूर्य का नतकाल मान कथित है, तीस ३० में उस घटिका को
घटाने से जो शेष रहता है उतनी ही संख्या करके चन्द्रनत होता है, किन्तु अर्धरात्र से विलोम
अर्थात् तिथ्यन्त में जितनी घटी में रवि नत होता है उनमें तीस ३० घटी को घटाकर जो शेष
रहता है वह चन्द्र का नत होता है, यदि रवि का प्राक्नत है तो चन्द्र का पश्चिमनत, यदि रवि
का पश्चिमनत है तो चन्द्र का प्राक्नत अर्धरात्र से होता है, सूर्यग्रहण में रवि जितनी घटी
करके नत रहता है उतनी ही घटी करके उसी काल में चन्द्र भी नत होता है इति ॥२५-२६॥

उपपत्ति

चन्द्रग्रहण पूर्णान्तकाल में होता है । पूर्णान्तकाल में रवि से चन्द्र छः राशि के
अन्तर पर रहता है इसलिये ऊर्ध्वयाम्योत्तरवृत्त से जितनी घटी करके रविनत रहता है,
उन घटी में तीस को घटा करके जो शेष रहता है उतनी घटी करके विपरीत कपाल में
चन्द्रनत होता है । सूर्यग्रहण में सूर्य और चन्द्र एक ही राश्याद्यवयव में रहते हैं इसलिये एक
कपाल में दोनों की तुल्य ही नत घटी होती है, सिद्धान्तशेखर में श्रीगति ने आचार्योक्तानु-
रूप ही कहा है । उनके पद्य संस्कृतोपपत्ति में देखिये इति ॥२५-२६॥

अब प्रकारान्तर से नतकर्म को कहते हैं

हि. भा.—पहले दिनदल (दिनार्ध) परिधियों से जो स्पष्टरवि और स्पष्टचन्द्र
साधित हैं उनसे जो तिथ्यन्त हैं तात्कालिक नतज्या और केन्द्रज्या के घात करना, यदि वह
रवि का है (अर्थात् रवि की नतज्या और रवि की केन्द्रज्या का घात है) तब उसको १९१ इससे
गुणाकर त्रिज्यावर्ग १०६९२९०० से भाग देना, यदि वह घात चन्द्र का है (अर्थात् चन्द्र-
नतकालज्या और चन्द्रकेन्द्रज्या का घात है) तब उसको ४९६ इससे गुणाकर त्रिज्यावर्ग
१०,६९,२९०० से भाग देना, दोनों स्थानों में जो विकलात्मक फल होता है पूर्वनत में सूर्य में
ऋण करना, पश्चिम नत में सूर्य में घन करना, चन्द्र में प्राक् कपाल में ऋणात्मक मन्दफल रहने
पर उस पूर्वागत केन्द्रफल को घन करना, अन्यथा प्राक् कपाल और पश्चिम कपाल में ऋण
ही करना चाहिये, इस तरह असकृत्कर्म करने से स्फुटरवि और स्फुटचन्द्र होते हैं । पहले
'तद्बहुदलपरिध्यन्तरगुणा' इत्यादि से नतकर्म साधित है, यहां पुनः उसका साधन किया
गया है इसलिये 'वा' शब्द का प्रयोग किया गया है इति ॥ २७-२८ ॥

उपपत्ति

$$\text{दिनार्धपरिधि से पूर्व प्रकार से मन्दफलकला} = \frac{२२५ \times \text{दिप} \times \text{ज्याके}}{२१४ \times ३६०} \text{ विकलात्मक}$$

करने से $\frac{२२५ \text{ दिप} \times \text{ज्याके} \times ६०}{२१४ \times ३६०}$, रवि के परिध्यन्तर = $\frac{\text{ज्यान}}{३ \text{ त्रि}}$ तब अनुपात करते हैं

यदि दिनार्ध परिधि में पूर्वागत मन्दफल विकला पाते हैं तो आनीत (लाये हुये)

परिध्यन्तर में क्या इस अनुपात से रवि की परिध्यन्तर मन्त्रान्धनी फल विकला

$$= \frac{६० \text{ दिप} \times २२५ \text{ ज्याके.ज्यान}}{३ \times २१४ \times ३६० \times \text{त्रि} \times \text{दिप}} = \frac{२० \times २२५ \text{ ज्याके.त्रि. ज्यान}}{२१४ \times ३६० \times \text{त्रि}^३}$$

$$= \frac{२२५ \times ३२७० \text{ ज्याके. ज्यान}}{१८ \times २१४ \times \text{त्रि}^३} = \frac{२५ \times १६३५ \text{ ज्याके.ज्यान}}{२१४ \times \text{त्रि}^३} = \frac{४० = ७५}{२१४}$$

× ज्याके.ज्यान $\frac{१११ \text{ ज्याके.ज्यान}}{\text{त्रि}^३}$, इसी तरह चन्द्र परिध्यन्तर से चन्द्र के गुणकाङ्क

आते हैं इति । सिद्धान्तशेखर में 'तत्तिथ्यन्तनतोद्भवोत्क्रमगुणः इत्यादि' मंस्कृतोपपत्ति में लिखित श्लोक से श्रीपति आचार्योक्तानुरूप ही कहते हैं, केवल आचार्य ने ३२७० एतत्तुल्य त्रिज्या ग्रहण किया है और श्रीपति ने ३४१५ त्रिज्याग्रहण किया है, तजन्त्य भाज्य और भाजक में थोड़ा अन्तर होना उचित ही है, आचार्योक्तनतज्या के स्थान में श्रीपति ने नतोत्क्रमज्या को ग्रहण किया है । इसका कारण केवल ललाचार्यानुयायिचतुर्वेदाचार्य का व्याख्यान ही है ॥२७-२८॥

इदानीं भुजान्तरकर्म स्पष्टगतिं चाह

अर्कफलभुक्तिघाताद् भगणकलाप्तं भुजान्तरं रविवत् ।

पूर्वप्रदर्शितयुक्त्यैव स्फुटमिति ॥ २६ ॥

अब भुजान्तरकर्म को और स्पष्ट गति को कहते हैं

हि. भा.—रवि के मन्दफल और ग्रहणगति के घात में भगणकला से भाग देने
से जो फल होता है, वह भुजान्तर कला है, ग्रह में उसको रवि की तरह संस्कार करना अर्थात्
ऋणात्मक रविमन्दफल में मध्यमार्कोदय से स्फुटार्कोदय पहले होता है इसलिये

मध्यमार्कोदयकालिक ग्रह में भुजान्तरफल को ऋण करने में स्फुटार्कोदयकालिक ग्रह होते हैं, घनात्मक रविमन्दफल में मध्यमार्कोदय से स्फुटार्कोदय पीछे होता है इसलिये मध्यमार्कोदय कालिक ग्रह में भुजान्तरफल को घन करने में स्पष्टार्कोदयकालिक ग्रह होते हैं, और रविदिन के ग्रह और एष्य दिन के ग्रह के अन्तर (दिवान्तर स्पष्ट ग्रहान्तर) वर्तमान दिन में स्पष्टगति होती है अर्थात् अद्यतन (आज के) स्पष्टग्रह और दृक्स्थान (कल के) स्पष्टग्रह का अन्तर स्पष्टगति होती है, यहाँ भगण कलाचन्द से अहोरात्रासु समझना चाहिये इति ॥ २६ ॥

उपपत्ति

मध्यमार्कोदयकालिक ग्रह में जितना संस्कार करने में स्फुटार्कोदयकालिक ग्रह होते हैं उसी को भुजान्तरकर्म कहते हैं । अहर्गण से माधित ग्रह आचार्य के मत से लङ्का सूर्योदय काल में मध्यम होते हैं, अर्थात् मध्यमार्कोदयकालीन होते हैं, स्फुटार्कोदय कालीन ग्रह अपेक्षित हैं, मध्यमार्क और स्फुटार्क का अन्तर रविमन्दफल कला है, इसके बराबर ही रविमन्दफलोत्पन्नासु आचार्य ने स्वीकार किये हैं, अब अनुपात करते हैं यदि अहोरात्रासु में ग्रहगति कला पाते हैं तो रविमन्दफलासु में क्या इस अनुपात से रविमन्दफलासुसम्बन्धिनी ग्रहगति आती है, मन्दफल ऋण रहने से मध्यमार्कोदय से पहले ही स्फुटार्कोदय होता है इसलिये अनुपातागत रविमन्दफलासुसम्बन्धिनी गति को मध्यमार्क में घटाने से स्फुटार्कोदय काल में स्फुटार्क होते हैं । इसी तरह उस गति को ग्रह में घटाने से स्फुटार्कोदय कालिक ग्रह होते हैं । घनात्मक रविमन्दफल में मध्यमार्कोदय से स्फुटार्कोदय पीछे होता है इसलिये पूर्वानीन चालनफल को मध्यमार्क में जोड़ने से स्फुटार्कोदयकालिक स्फुटार्क होते हैं, ग्रह में चालनफल को जोड़ने से स्पष्टार्कोदयकालिक ग्रह होते हैं, यहाँ स्थूलता स्पष्ट ही है क्योंकि रविमन्दफलकला के बराबर ही रविमन्दफलासु को आचार्य ने स्वीकार किया है । दूसरी त्रुटि इसमें यह है कि मध्यमार्कोदयकालिक ग्रह में पूर्वानुपातागत रविमन्दफलासुसम्बन्धिनी गति का संस्कार करने से स्फुटार्कोदयकालिक ग्रह नहीं हो सकते हैं क्योंकि रविमन्दफलासु के अन्तर्गत भी ग्रह की कुछ गति होगी उसका ग्रहण आचार्य ने नहीं किया है वास्तव भुजान्तर ज्ञान के लिये उसी विधि का आश्रय करना चाहिये जो कि पहले वास्तवउदयान्तर ज्ञानार्थ दिखलायी गई है, वास्तव उदयान्तर साधन में प्राचीनोदयान्तर के स्थान पर प्राचीन भुजान्तर लेना चाहिये और सब विषय बराबर ही है, सूर्यसिद्धान्तकारादि किसी भी आचार्य के भुजान्तरकर्मसाधन ठीक नहीं है, पहले लिखी हुई युक्ति ही से स्पष्ट है इति ॥ २६ ॥

अत्रोपपत्तिः

प्रथमपदे तृतीयपदे च केन्द्रज्योपचीयते, द्वितीयपदे चतुर्थपदे चापचीयते, रवेः
प्राक्कपाले नतकम ऋणं पश्चिमकपाले च धनं भवति, अतः प्रथमपदे तृतीयपदे च
ऋणफलस्योपचयान्नतकमन्ति रमृणं द्वितीयपदे चतुर्थपदे च ऋणफलस्यापचयान्नत-

कर्मन्तरं धनं भवति, पश्चिमकपाले नतकर्मणो धनत्वाद्धिदोमं भवति । चन्द्रस्य पश्चिमकपाले मन्दफले ऋणो धने च नतकर्म ऋणमेव भवत्यतः केन्द्रादवधान् क्षयधनहानिधनानि फलानि जायन्ते, पूर्वकपाले प्रथमपदे ऋणात्मके मन्दफले केन्द्रज्याया उपचयत्वात् नतकर्मणो धनत्वाच्च नतकर्मन्तरं धनं भवति, द्वितीयपदे केन्द्रज्याया अपचयत्वात् नतकर्मन्तरमृणं, तृतीयपदे मन्दफलं धनं नतकर्म ऋणं केन्द्रज्यायाश्चोपचयोऽतो नतकर्मन्तरमृणम्, चतुर्थे पदे केन्द्रज्याया अपचयत्वात् नतकर्मणश्च क्षयत्वात् नतकर्मन्तरं धनं भवतीति । दिनान्तरस्पष्टग्रहान्तरं स्पष्टा गति-
भवतीति नियमाद् गनदिननतकाल एव द्वितीयदिनेऽपि नतकालस्तेन केन्द्रज्या एवोपचयापचयवशात् नतकर्मन्तररूपद्वितीयगतिफलस्य धनत्वात्वं समुचित-
मेवेति ॥ ३० ॥

अब नत कर्मवश से रवि और चन्द्र के गतिफल को कहते हैं

हि. भा.—दिनदलपरिधिस्फुटतिथिनतकेन्द्रज्या इत्यादि ने ग्रहगतन और श्वस्तन फल विकलाओं के अन्तर (विकलात्मक अन्तर) पूर्वकपाल में पूर्वसाधितरविमन्दस्पष्ट गति में रवि के केन्द्रपदवश से ऋण, धन, ऋण, धन होता है । पश्चिम कपाल में विलोम होता है अर्थात् धन, ऋण, धन, ऋण, चन्द्र के पश्चिम कपाल में पूर्ववत् होता है अर्थात् ऋण, धन, ऋण, धन, और पूर्व कपाल में चन्द्रमन्दस्पष्टगति में वे ही धन, ऋण, ऋण, धन होते हैं ॥३०॥

उपपत्ति

प्रथम पद में और तृतीय पद में केन्द्रज्या उपचीयमान रहती है और द्वितीय पद में तथा चतुर्थ पद में अपचीयमान रहती है; रवि के पूर्व कपाल में नतकर्म ऋण और पश्चिम कपाल में धन होता है इसलिये प्रथम पद में और तृतीय पद में ऋणफल के उपचय के कारण नतकर्मन्तर ऋण होता है । द्वितीय और चतुर्थ पद में ऋण फल के अपचयत्व के कारण नतकर्मन्तर धन होता है, पश्चिम कपाल में नतकर्म के धनत्व के कारण विलोम (उल्टा) होता है, चन्द्र के पश्चिम कपाल में मन्द फल के ऋण या धन रहने पर नतकर्म ऋण ही होता है । इसलिए केन्द्रपदवश से फल ऋण, धन, ऋण, धन होता है । द्वितीय पद में केन्द्रज्या के अपचयत्व के कारण नतकर्मन्तर ऋण होता है । तृतीय पद में मन्दफल धन, नतकर्म ऋण, केन्द्रज्या का अपचय रहता है । इसलिये नतकर्मन्तर ऋण होता है, चतुर्थ पद में केन्द्रज्या के अपचयत्व से और नतकर्म के क्षयत्व के कारण नतकर्मन्तर धन होता है । ग्रहगतन (आज के) श्वस्तन (कल के) स्पष्टग्रहों का अन्तर स्पष्ट गति है । इस नियम से गत-
दिन का नतकाल ही द्वितीय दिन में भी नतकाल होता है इसलिये केन्द्रज्या ही के उपचय और अपचय वश से नतकर्मन्तर रूप द्वितीय गति फल का धनत्व और ऋणत्व उचित ही है इति ॥३०॥

इदानीमाचार्यः स्वप्रशंसामाह

ब्रह्मोक्तमध्यरविशशितदुच्चतत्परिधिभिः स्फुटीकरणम् ।

कृत्वैवं स्पष्टतिथिदूर्भ्रष्टान्यतन्त्रोक्तैः ॥३१॥

वा. भा.—श्लोकस्यास्य वासनाभाष्यं नोपलभ्यते ।

वि. भा.—ब्रह्मोक्त (ब्रह्मगुप्तकथित) मध्यरविचन्द्रतन्मन्दोच्चतत्परिधिभिः स्फुटीकरणं कृत्वा स्पष्टतिथिः साध्या यतोऽन्यतन्त्रोक्तैः (अन्येषामार्यभटादीनां तन्त्रेषु ये कथिता मध्यरविशशितपरिध्यादयस्तैः) स्पष्टतिथिदूर्भ्रष्टा भवत्यर्थादत्यन्तनिषिद्धा भवत्येतावताऽऽचार्येण कथ्यते यन्मत्कथितस्पष्टीकरणसामग्रीभिरेव रविचन्द्रयोः स्पष्टीकरणं युक्तियुक्तं, ताभ्यां स्पष्टीकृताभ्यामेव रविचन्द्राभ्यां साधिता स्पष्टा तिथिः समीचीना भवति, आर्यभटादिकथितस्पष्टरविचन्द्रसामग्रीभिर्वस्तुतः स्पष्टौ रविचन्द्रौ न भवतोऽतस्ताभ्यां साधिता तिथिः स्पष्टा न भवतीति ॥३१॥

अब आचार्य अपनी प्रशंसा कहते हैं

हि. भा.—ब्रह्म (ब्रह्मगुप्त) कथित मध्यरवि, मध्यमचन्द्र, उनके मन्दोच्च और उनकी मन्द परिधि इन सबों से रवि और चन्द्र के स्पष्टीकरण करके स्पष्ट तिथि का साधन करना चाहिये, क्योंकि आर्यभटादि अन्य आचार्यों के तन्त्रों में कथित मध्यरवि, मध्यमचन्द्र और उनकी मन्द परिधियों से साधित स्पष्टतिथि वस्तुतः स्पष्टतिथि नहीं होती है इससे आचार्य कहते हैं कि मेरी स्पष्टीकरण सामग्रियों से ही रवि और चन्द्र का स्पष्टीकरण युक्तियुक्त होता है, उन स्पष्टीकृत रवि और चन्द्र से साधित स्पष्टतिथि यथार्थ स्पष्टतिथि होती है, आर्यभटादि आचार्यों से कथित स्पष्टरवि और स्पष्टचन्द्र की सामग्रियों से वस्तुतः स्पष्टरवि और स्पष्टचन्द्र ठीक नहीं होते हैं इसलिये उन रवि और चन्द्र से साधित स्पष्ट तिथि ठीक स्पष्ट तिथि नहीं होती है इति ॥३१॥

इदानीं व्यवहारोपयुक्तरविचन्द्रयोः स्पष्टीकरणमाह

स्वदिनार्धपरिधिभुजफलचापं मध्यार्कचन्द्रयोः कृत्वा ।

पूर्ववदन्यत् स्पष्टं संव्यवहारार्थमेवं वा ॥३२॥

वा. भा.—अस्य श्लोकस्य वासनाभाष्यं नास्ति ।

वि. भा.—स्वदिनार्धपरिधिना पूर्वकथितविधिना यद्भुजफलचापं (मन्दफलं) तन्मध्यमरविचन्द्रयोः संस्कृत्य अन्यद्देशान्तरादिसं कारं पूर्ववत् कृत्वैवं वा संव्यवहारार्थं स्पष्टीकरणं विधेयम् । नतकर्मसंस्कारं विनैवाऽऽचार्येणोदं स्पष्टीकरणं स्थूलं व्यवहारोपयोगिकथितम् । भास्कराचार्येण रविचन्द्रयोः स्थूलमेवेदं स्पष्टी-

करणं सर्वकर्मोत्पत्तं सूक्ष्मत्वेन स्वीकृतम् । 'मुहुः स्फुटाज्जो ग्रहणो रवीन्द्रोऽस्त्या-
दिना' भास्करेण यदाचार्यमतं वर्णितं वस्तुतस्तत्तन्मतं नास्तीति विज्ञेयोध्य-
मिति ॥३२॥

अब व्यवहारोपयोगी रवि और चन्द्र के स्पष्टीकरण को कहते हैं

हि. भा.—स्वदिनार्धपरिधि से पूर्वकथित विधि के अनुसार जो मन्दभुजफल होता है उसके चाप (मन्दफल) को मध्यमरवि और मध्यमचन्द्र में संस्कार करके अन्य देशान्तरादि संस्कारों को पूर्ववत् करके व्यवहार के लिये वा इस तरह स्पष्टीकरण करना चाहिए । बिना नतकर्म संस्कार के आचार्य इस व्यवहारोपयोगी स्थूल स्पष्टीकरण को कहते हैं । 'भास्करा-
चार्य ने रवि और चन्द्र के इस स्थूल स्पष्टीकरण को ही सूक्ष्म सब कर्मों के लिये उपयुक्त स्वीकार किया है, 'मुहुः स्फुटाज्जो ग्रहणो रवीन्द्रोः इत्यादि से' भास्कराचार्य ने आचार्य-
मत का भिन्न तरह प्रतिपादन किया है इति ॥३२॥

इदानीं मङ्गलादिग्रहस्पष्टीकरणे कारणमाह

आर्यभटस्याज्ञानान्मध्यममन्दोच्चशीघ्रपरिधीनाम् ।

अस्पष्टा भौमाद्याः स्पष्टा ब्रह्मोक्तमध्योच्चैः ॥३३॥

वा. भा.—नास्ति वासनाभाष्यमस्य श्लोकस्य ।

वि. भा.—आर्यभटस्य मध्यममन्दोच्चशीघ्रपरिधीनामज्ञानात्कारणात्,
भौमाद्या (मङ्गलादिकाः) ग्रहाः अस्पष्टा भवन्त्यतो ब्रह्मो (ब्रह्मगुप्तो) त्तमध्योच्चै-
र्भौमाद्याः स्पष्टाः कार्या अर्थादार्यभटस्य वास्तवमध्यममन्दोच्चादीनामज्ञानात्तन्मतेन
भौमादिग्रहस्पष्टीकरणं न युक्तमतो मदुक्तवास्तवमन्दोच्चादीस्तत्स्पष्टीकरणं विधेय-
मिराचार्याभिप्राय इति ॥३३॥

अब मङ्गलादि ग्रहों के स्पष्टीकरण में कारण कहते हैं

हि. भा.—आर्यभट को वास्तव मध्यममन्दोच्च-शीघ्र परिधियों का ज्ञान नहीं था
इसलिये भौमादि (मङ्गल आदि) ग्रह उनके मत से स्पष्ट नहीं होते हैं । ब्रह्मो (ब्रह्मगुप्तो) त्त
मन्दोच्चादि से वे स्पष्ट होते हैं, आचार्य के कहने का तात्पर्य यह है कि आर्यभट को मध्यम
मन्दोच्च शीघ्र परिधियों का ज्ञान नहीं था इसलिये हमारे मन्दोच्चादि से कुजादि ग्रहों के
स्पष्टीकरण करने से वे ठीक स्पष्ट होते हैं इति ॥३३॥

अब मङ्गलादि ग्रहोंके मन्द परिध्यंश, शीघ्र परिध्यंश

और स्पष्टीकरण को कहते हैं ।

शुक्र के विषम पदान्त में मन्दोच्चनीचवृत्त परिध्यंश नव ६ होता है और सम पदान्त में ग्यारह होता है, विषम पदान्त में शीघ्र परिध्यंश २६३, और सम पदान्त में २५८ होते हैं । मध्यम ग्रह में मन्द फल के संस्कार करने से मन्द स्पष्ट ग्रह होता है । मन्द स्पष्ट ग्रह में शीघ्र फल संस्कार करने से असकृत्प्रकार से स्पष्ट ग्रह होते हैं अर्थात् मध्यम ग्रह से फिर मन्दफल साकर मध्यमग्रह में संस्कार करने से मन्दस्पष्टग्रह होते हैं । उस (मन्दस्पष्टग्रह) से पुनः शीघ्र फल साकर मन्दस्पष्टग्रह में संस्कार करने से स्पष्टग्रह होते हैं । पुनः इस स्पष्ट ग्रह से पूर्ववत् मन्दस्पष्टग्रह और स्पष्टग्रह साधन करना जब तक बिलकुल ठीक हो

जाय तब तक करना चाहिये, बुध, बृहस्पति और शनिश्चर मन्दफलों और शीघ्रफलों से पूर्ववत् असकृत् कर्म से स्फुट होते हैं। बुध के मन्दपरिध्यंश = ३८°, बृहस्पति के = ३३°, शनिश्चर के मन्दपरिध्यंश = ३०°, विषमपदान्त में और समपदान्त में अर्थात् इन ग्रहों के मन्द-परिध्यंशों में संस्काराभाव होता है, बुध के शीघ्र परिध्यंश = १३२°, बृहस्पति के = ६८°, शनि के = ३५°, इन शीघ्र परिध्यंशों में भी संस्काराभाव होता है, अर्थात् बराबर स्थिर (एकरूप) परिध्यंश होता है, मङ्गल का शीघ्रकेन्द्र जिस पद में हो उसमें गत केन्द्रांश और गम्य केन्द्रांश में जो भ्रम हो उसकी ज्या को तृतीयांश रहित सात अंश ६' ४०" से गुणा कर पैंतालीस अंश की ज्या से भाग देने से लब्ध जो अंश हो उस को मकरादिशीघ्र केन्द्र में मङ्गल के मन्दोच्च में जोड़ने से और कर्क्यादि केन्द्र में घटाने से स्पष्टीकरणोपयुक्त मङ्गल का मन्दोच्च होता है, उन (मङ्गल) के मन्दपरिध्यंश = ७०°, और २४३' ४०" इन में मन्दोच्च संस्कारार्थ पहले जो अंश प्राप्त हुये थे उनको हीन करने से मङ्गल की स्फुटशीघ्रपरिधि होती है। मङ्गल का स्पष्टीकरण आगे लिखे हुए नियम के अनुसार होता है। गणितागत मङ्गल में यथागत मन्दफल के भावे को घन या ऋण करना, उस मन्द फलार्थ संस्कृत मध्यम मङ्गल से शीघ्रफल साधन करना, उस के भावे को मन्दफलांश संस्कृत मध्यम मङ्गल में देना, मन्दफलांश और शीघ्र फलांश संस्कृत मध्यम मङ्गल से जो मन्दफल हो मध्यम मङ्गल में उस को संस्कार कर के जो हो उस से शीघ्रफल साधन करना, वे दोनों (मन्दफल और शीघ्रफल) गणितागत मङ्गल में देना, बाद में बुध, बृहस्पति और शनि की तरह असकृत्कर्म तब तक करना चाहिये जबतक बिलकुल ठीक हो जाय, तब मङ्गल स्फुट होते हैं। ग्रह की तरह स्पष्टगति साधन करना, अद्यतन अस्तन ग्रहों का अन्तर स्पष्टग्रहगति होती है इति ॥३४-३५-३६-३७-३८-३९-४०॥

उपपत्ति

ब्रह्मगुप्तोक्त शनि की शीघ्रपरिधि = ३५°, सूर्यसिद्धान्तोक्त शनि की शीघ्रपरिधि = ४०°, भास्करोक्तशनिशीघ्रप = ४०, आचार्योक्त शनिमन्दपरिध्यंश = ३०°, भास्करोक्तशनि-मन्दपरिध्यंश = ५०°, शनि के परिध्यंशों में भास्कराचार्य आचार्योक्त से भिन्न क्यों कहे हैं इस को वे ही जान सकते हैं, सूर्यसिद्धान्तकार शीघ्रान्त्यफलज्या भी सदा स्थिर नहीं है इस बात को मन में रख कर समपदान्त और विषम पदान्त भेद से भिन्न-भिन्न परिध्यंश बताये हैं, जैसे 'कुजादीनामतः शैध्या युग्मान्तेऽर्ध्वाग्निदक्षकाः इत्यादि' संस्कृतोपपत्ति में लिखा गया है, आचार्य (ब्रह्मगुप्त) ने जिस तरह परिधि का स्पष्टीकरण किया है तदनुरूप ही भास्कराचार्य ने भी अपनी सिद्धान्तशिरोमणि में कहा है, मङ्गल के चारों शीघ्र केन्द्र पदान्त में गणितागत मन्दोच्च एक ही रूप का होता है, पदमध्य में तृतीयांश (२० कला) रहित सात अंश ६' ४०" करके न्यून होता है, इसलिये इन दोनों के मध्य में अनुपात करते हैं, यदि पैंतालीस अंश शीघ्रकेन्द्रांश की ज्या में तृतीयांशोन सात अंश ६' ४०" मन्दोच्चान्तर पाते हैं तब इष्टशीघ्रकेन्द्र पद में गत और गम्य में भ्रम शीघ्र केन्द्रज्या में क्या इस अनुपात से जो फल आता है उसको मकरादि केन्द्र में और कर्क्यादिकेन्द्र में गणितागत

मङ्गल के मन्दोच्च में युत और हीन करने से स्फुटमन्दोच्च होता है, तथा मङ्गल के पदान्तों में शीघ्रपरिधि एकरूपक ही होती है, पदमध्य में तृतीयांशोन सात अंश ६'।४०' करके सदा न्यून ही होता है, दोनों के मध्य में पूर्वानुपातागत फल को उनके शीघ्र परिधिप्रमाण में घन और ऋण करने से स्फुट शीघ्रपरिधि होती है, आचार्योक्तानुरूप ही भास्कराचार्य कहते हैं। ग्रहस्पष्टीकरण में मङ्गल और शुक्र ही में अन्तर तथा मङ्गल के मन्दोच्च में वैषम्य को आचार्य देखे, इस में कोई युक्ति नहीं कही गयी है, केवल वेध ही प्रमाण है, यह बात भास्कराचार्य के कथन से मान्य होती है, सिद्धान्तशेखर में श्रीपति ने 'भोमो निते दितकरे पदयातयेयन्यूनज्यका' इत्यादि संस्कृतोपपत्ति में लिखित श्लोक से आचार्योक्तानुरूप ही मङ्गल के मन्दोच्चस्फुटीकरण को कहा है, पद में गत केन्द्रांश और गम्य केन्द्रांश में जो अल्प है उस की ज्या के तृतीयांशोन सात अंश के गुणकाङ्क स्थान में ३७ = गुणक और पैंतालीस अंश ज्यात्मक भाजक स्थान में बारहवीज्या = २१४५ तुल्य भाजक को ५ इससे अपवर्त्तन देकर गुणक स्थान में चार ४, और भाजक स्थान में १४४६ किया तथा 'नीचोच्चवृत्तं क्षितिजस्य मान्दं' इत्यादि संस्कृतोपपत्ति में लिखित श्रीपति की उक्ति 'तत्स्फुटपरिधिः खनगाः' इत्यादि आचार्योक्त के अनुरूप ही है, तथा 'मृदुफलदलमादौ मध्यमे मेदनीजे' इत्यादि श्रीपति प्रकार का तथा 'दलीकृताभ्यां प्रथमफलाभ्यां' इत्यादि भास्करोक्त प्रकार का मूल 'मन्दफलं मध्येऽर्धं तच्छीघ्रफलस्य मध्यमे' इत्यादि आचार्योक्त प्रकार ही है इति ॥ ३४-३५-३६-३७-३८-३९-४०॥

अब ग्रहों की मन्दस्पष्टगति और स्पष्टगति को कहते हैं

हि. भा.—मन्दकेन्द्र गति को ज्यान्तर (भोग्यखण्ड) से गुणाकर प्रथमज्या से भाग
 देकर जो लब्धि हो उसको स्फुट परिधि से गुणाकर भगसांश ३६० से भाग देकर जो लब्धि
 कला हो उसको मकरादि केन्द्र में अपनी मध्यम गति में घटाने से और कर्क्यादिकेन्द्र में जोड़ने
 से रवि और चन्द्र की स्पष्टगति होती है, अपनी मध्यगति में मन्दगति फल को संस्कार करने
 से कुजादि ग्रहों की मन्दस्पष्टगति होती है, अपनी मन्दस्पष्टगति को शीघ्रोच्चगति में
 घटाने से कुजादि ग्रहों की शीघ्रकेन्द्रगति होती है, शीघ्रकेन्द्रगति को भोग्य खण्ड से
 गुणा कर प्रथमज्या से भाग देने से जो लब्धि हो उसको व्यासार्ध (त्रिज्या) से गुणा कर
 शीघ्रकर्ण से भाग देने से जो लब्धि हो उसको शीघ्रोच्चगति में घटाने से स्फुटगति होती है,
 यदि लब्धि शीघ्रोच्चगति से अधिक हो तब लब्धि में शीघ्रोच्चगति को घटाकर जो शेष
 रहता है वह कुजादि (मङ्गलादि) ग्रहों की वक्रगति होती है, इति ॥४१-४२-४३-४४॥

उपपत्ति

मध्य और स्पष्टभेद मे गति दो तरह की होती है, प्रतियोग में जो गति भिन्न होती है, वह स्पष्टगति है, जो प्रतियोग में भिन्न नहीं होती है वह मध्यगति है। स्पष्टगति भी दैनिक और तात्कालिक भेद मे दो प्रकार की होती है, दैनिकमन्दस्पष्टगति, तात्कालिक-मन्दस्पष्टगति, दैनिकस्पष्टगति, तात्कालिकस्पष्टगति, आचार्य दैनिकमन्दस्पष्टगति और स्पष्टगति का साधन करते हैं। संस्कृतोपपत्ति में लिखित (क) क्षेत्र को देखिये।

भू=भूकेन्द्र, भूल=मन्दान्त्यफलज्या, ल=ग्रहमन्दगोलकेन्द्र, अ=मन्दप्रतिवृत्त में गणितागनमध्यमग्रह। उ=मन्दोच्च, अउ=मन्दकेन्द्र, अल=मन्दभुजफल=मन्दफलज्या स्वल्पान्तर से, अअ=भूर=मन्दकेन्द्रज्या, अल=मन्दान्त्यफलज्या, भूरग, अलन दोनों त्रिभुज सजातीय हैं इसलिये अनुपात करते हैं,

$$\frac{\text{मंकेज्या} \times \text{मंअंफज्या}}{\text{त्रि}} = \text{अद्यतनभुजफल} = \text{अद्यतनमन्दफलज्या}, = \text{मंफज्या},$$

$$\frac{\text{मंकेज्या} \times \text{मंअंफज्या}}{\text{त्रि}} = \text{श्वस्तनभुजफल} = \text{श्वस्तनमंदफलज्या} = \text{मंफज्या},$$

दोनों का अंतर करने से

$$\frac{\text{मंअंफज्या}}{\text{त्रि}} (\text{मंकेज्या} - \text{मंकेज्या}) = \frac{\text{मंअंफज्या} \times \text{मंकेज्यान्तर}}{\text{त्रि}} = \text{मंफज्या} - \text{मंफज्या} =$$

मन्दफलज्यान्तर=मन्दफलान्तर=मंगतिफल

स्वल्पान्तर से, परन्तु $\frac{\text{मन्दकेग} \times \text{भोलं}}{\text{प्रथमज्या}} = \frac{\text{मंकेग} \times \text{भोलं}}{\text{प्रथमज्या}} = \text{मन्दकेन्द्रज्यान्तर}$, उत्थापन देने से

$$\frac{\text{मंअंफज्या}}{\text{त्रि}} \times \frac{\text{मंकेग} \times \text{भोलं}}{\text{प्रथमज्या}} = \text{मंगतिफल}। \text{परन्तु } \frac{\text{मंअंफज्या}}{\text{त्रि}} = \frac{\text{मंपरिधि}}{\text{भाग}} = \frac{\text{मंपरिधि}}{३६०}$$

अतः $\frac{\text{मंपरिधि}}{३६०} \times \frac{\text{मंकेग} \times \text{भोलं}}{\text{प्रथमज्या}} = \text{मंगतिफल}$, इससे आचार्योंक्त उपपन्न हुआ, सिद्धान्तशेखर में

“मन्दकेन्द्रगतिरकंचन्द्रयोः” इत्यादि संस्कृतोपपत्ति में लिखित श्रीपत्युक्तप्रकार, तथा सूर्यसिद्धान्तकारोक्त मन्दगति फलानयनप्रकार भी उपपन्न हुआ, उसी मन्दगतिफलस्वरूप में भांश और परिध्यांश को $\frac{१}{६}$ इससे अपवर्तन देने से मन्दगतिफल

$$= \frac{\text{मंकेग} \times \text{भोलं}}{\text{प्रज्या}} \times \frac{२ \text{ परिधि}}{६} = \frac{\text{मंकेग} \times \text{भोलं}}{\text{प्रज्या}} \times \frac{\text{स्फुगुणक}}{६०}, \frac{२ \text{ परिधि}}{६} = \text{स्फुगुणक}$$

$$\frac{२ \times ३६०}{६}$$

इससे 'ज्यःखण्डकेन गुणिता' इत्यादि संस्कृतोपपत्ति में लिखित लल्लोक्त मन्दगतिफलानयन उपपन्न होना है, मन्दगतिफलानयन किसी भी आचार्य का ठीक नहीं है, यह पूर्वोक्तोपपत्ति देखने ही में स्पष्ट है। केवल भास्कराचार्योक्त मन्दगतिफलानयन ठीक है, यद्यपि बटेश्वर-सिद्धान्त में इन विषय को हम दिखला चुके हैं, तथापि यहाँ लिखते हैं।

मंग्रंज्या. मंकेज्या
त्रि = मंगज्या, दोनों पक्षों की तात्कालिक गति लेने से

$$\frac{\text{मंग्रंज्या}}{\text{त्रि}} \times \frac{\text{मंकेज्या. मंकेग}}{\text{त्रि}} = \frac{\text{मंगफ. मंकोज्या}}{\text{त्रि.}} \quad \text{अतः} \quad \frac{\text{मंग्रंज्या}}{\text{त्रि}} \times \frac{\text{मंकेज्या. मंकेग}}{\text{त्रि}}$$

$$\times \frac{\text{त्रि}}{\text{मंकोज्या}} = \frac{\text{मंकोफ. मंकेग}}{\text{त्रि}} \times \frac{\text{त्रि}}{\text{मंकोज्या}} = \frac{\text{भास्करोक्तमन्दगतिफल. त्रि}}{\text{मंकोज्या}} = \text{मन्दगतिफल,}$$

$$\therefore \frac{\text{मंकोफ. मंकेग}}{\text{त्रि}} = \text{भास्कर मंगफ.,}$$

इससे सिद्ध हुआ कि भास्करोक्त मन्दगतिफल को त्रिज्या से गुणाकर मन्दफलकोटिज्या से भाग देने से वास्तवमंदगति फल होता है, इससे 'भास्करोक्तं गतिफलं त्रिज्यया गुणितं' इत्यादि संस्कृतोपपत्ति में लिखित म. म. सुधारक द्विवेदी जी का सूत्र भी उपपन्न होता है।

मन्दस्पष्टगति प्रमाण लाते हैं

प्रथम पद में और द्वितीय पद में (मकरादि केन्द्र में) अद्यतनमध्यग्र—अद्यतनमंग
= अद्यतनमंसग्र

श्वस्तनमध्यग्र—श्वस्तनमंग=श्वस्तनमंसग्र

दोनों का अंतर करने से

कुजादि ग्रहों की मध्यगति—मन्दगतिफल = मंदस्पष्टगति,

तृतीय पद में और चतुर्थ पद में (कर्क्यादिकेन्द्र में) अद्यतनमध्यग्र + अद्यतनमंग

= अद्यतनमंसग्र.

श्वस्तनमध्यग्र + श्वस्तनमंग = श्वस्तनमंसग्र.

दोनों का अन्तर करने से

कुजादि ग्रहों की मध्यगति + मंगतिफल = मंदस्पष्टगति

रविमध्यगति + रमंगतिफल = स्परविगति

एवं चंमध्यगति + चंमंगतिफल = चंस्पष्टगति

अब स्पष्टगति साधन के लिये उपपत्ति

$\frac{\text{शीकेज्या.त्रि}}{\text{शीक.}} = \text{स्पकेज्या, द्वितीय दिन में } \frac{\text{शीकेज्या. त्रि}}{\text{शीक.}} = \text{स्पकेज्या, यहां शीकेज्या} = \text{मन्द-स्पष्टकेन्द्रज्या, शीक} = \text{शीघ्रकरां.}$

दोनों का अन्तर करने से

$$\frac{\text{त्रि (शीकेज्या - शीकेज्या)}}{\text{शीक}} = \frac{\text{स्पकेज्या - स्पकेज्या}}{\text{शीक}} = \frac{\text{त्रि. शीकेज्यान्तर}}{\text{शीक}} = \text{स्पकेज्यान्तर}$$

$$\text{परन्तु. } \frac{\text{भोगं. शीकेग}}{\text{प्रथमचा}} = \text{शीकेज्यान्तर, उत्थापन करने से } \frac{\text{त्रि}}{\text{शीक}} \times \frac{\text{भोगं. शीकेग}}{\text{प्रथमचा}} = \frac{\text{त्रि}}{\text{शीक}}$$

$$\times \frac{\text{भोगं. शीकेग.}}{\text{प्रज्या}} = \text{स्पष्टकेज्यान्तर} = \text{स्पकेन्द्रान्तर} = \text{स्पकेग स्वल्पान्तर से}$$

∴ अद्यननशीउ — अद्यननस्पग = अद्यननस्पके, श्वस्तनशीउ — श्वस्तनस्पग = श्वस्तन-स्पके, दोनों का अन्तर करने से शीउग — स्पग = स्पकेग ∴ शीउग — स्पकेग = स्पग; यदि शीउग < स्पकेग तब विलोमशोधन से ऋणात्मिकागति = वक्रागति होती है, इससे आचार्योक्त उपपन्न हुआ। सिद्धान्तदोहर में ‘चञ्चलकेन्द्रगतिः फलभोग्यज्यागुणिता’ इत्यादि संस्कृतोपपत्ति में लिखित श्रीयत्युक्त, स्पष्टगति साधन आचार्योक्तानुरूप ही है, लल्ला-चार्योक्त स्पष्टगति साधन भी ऐसा ही है, लेकिन किसी भी आचार्य से कहा गया स्फुटगति साधन ठीक नहीं है, यह विषय पूर्वोक्तोपपत्ति देखने ही से स्पष्ट है, केवल सिद्धान्तशिरोमणि में ‘फलांगुलाङ्कान्तरशिञ्जिनीघ्नी’ इत्यादि से तात्कालिकस्पष्टगति से भास्करोक्त स्पष्ट-गति साधन सूक्ष्म है, इसको विवेचक लोग विचारें इति ॥४१-४२-४३-४४॥

अत्र विशेषविचारः

अत्र “फलांगुलाङ्कान्तरशिञ्जिनीघ्नी” त्यादि भास्करोपविधानेन—

$$\text{स्पष्टकेन्द्रगतिः} = \frac{\text{कोज्याफ} \times \text{शीकेग}}{\text{क}}$$

$$\text{अथवा स्पकेग} = \text{शीकेग} \div \text{गफ}$$

$$\therefore \text{शीकेग} \div \text{गफ} = \frac{\text{कोज्याफ} \times \text{शीकेग}}{\text{क}}$$

$$\text{वा शीकेग.क} \div \text{गफ.क} = \text{कोज्याफ.शीकेग.}$$

समीकरणेन—

$$\text{गफ} = \frac{\text{शीकेग (क} \div \text{कोज्याफ)}}{\text{क}} \dots \dots \dots (१)$$

एतेन “मन्दस्फुटीकृतां भुक्तिं प्रोज्झ्य शीघ्रोच्चभुक्तिरतः । तच्छेषं विवरेणासौ हन्यात्त्रिज्यान्त्यकर्णयो” रित्यादिसूर्यसिद्धान्तोक्तं शीघ्रगतिफलमुपपद्यते ।

अत्रैव गूढार्थप्रकाशे रङ्गनाथस्तु तात्कालिकया गत्या शीघ्रगतिफलं (१) समीकरणेन समानोय “त्रिज्यान्त्यकर्णयो” रित्यत्र सौरवचसि त्रिज्या-शब्देन शीघ्रफलकोटिज्यां परिगृह्य सौरमतं समर्थयति । अत्रैव सौरवासनायां कमनाकरैस्तु लल्लमतमण्डनार्थं त्रिज्यामेवाङ्गीकृत्य बहूपपादितम् । तन्नादरणीय-मिति मुधावर्षिण्यां तत्प्रणेतारः परमगुरुचरणा वदन्ति । त्रिषु राशिषु फलशोध-नेन या ज्या सैवात्र त्रिज्येत्यर्थं विधाय रङ्गनाथमतं समर्थयन्ति च अन्यथा “वृत्तद्वययोगे द्युचरे मध्यैव गतिः स्पष्टे” ति लल्लवचसा वृत्तद्वययोग एव सौरमतेनापि मध्यगतिः स्पष्टगतेः समा भवेत् । तन्न समीचीनम् । [“कक्षामध्य-गतिर्यग्रेत्वाप्रतिवृत्तसंपाते” तस्य समत्वसिद्धेः ।

इदानीं स्पष्टीकरणमिदं कस्मै न देयमित्याह

देयममुताय नेदं शपथैरपि दत्तमुकृतनाशाय ।

यात्राविवाहजातकफलस्फुटत्वं यतः स्पष्टैः ॥४५॥

वा. भा.—वासनाभाष्यं नास्ति ।

वि. भा.—यतः (यस्मात् कारणात्) स्पष्टैः (स्पष्टग्रहैरेव) यात्राविवाह-जातकफलानां स्फुटत्वं भवति, अतः शपथैरपीदं स्पष्टीकरणं असुताय (अपुत्राय) न देयमन्यथा दत्तमुकृतनाशाय (दातुः शोभनकर्मेनाशाय) भवति, केवलं भक्ताय, स्वान्ते चिरवासिने शिष्याय देयमिदमिति ॥४५॥

अब स्पष्टीकरण किसके लिये नहीं देना चाहिये कहते हैं

हि. भा.—जिस कारण से स्पष्टग्रहों ही से यात्रा-विवाह-जातकफलों की स्फुटना होती है, इसलिये शपथ खाने से भी इस स्पष्टीकरण को अपुत्र के लिये नहीं देना चाहिये अर्थात् भक्त, बहुत दिनों तक अपने पास रहने वाले विद्यार्थियों के लिये देना चाहिये, अपुत्र को देने से किये हुये सुन्दर कर्मों का नाश होता है इति ॥४५॥

इदानीमार्यभटादीनां दोषमाह

मेधादितः प्रवृत्ता नार्यभटस्य स्फुटा युगस्यादौ ।

श्रीषेणस्य कुजाद्याः खेदाः सर्वे हि विष्णुचन्द्रस्य ॥४६॥

न दृष्टाः स्पष्टाः श्रीषेणार्यभटविष्णुचन्द्रेषु ।

यस्मात्कुजादयस्ते विदुषां नैवादरस्तस्मात् ॥४७॥

वा. भा.—वासनाभाष्यं नास्ति ।

वि. भा.—आर्यभट्टस्य श्रीपिंगल-विष्णुचन्द्रस्य सर्वे कुजाद्याः वेदाः (मङ्गलादिग्रहाः) युगन्यादौ मेपादिनो न प्रवृत्ता अर्थान्कुजाद्याः सर्वे ग्रहा युगादौ मेपादौ नास्मन्नतन्मे स्पष्टा न सन्तीति, यस्मात्कारणान्-श्रीपिंगल-आर्यभट्ट-विष्णुचन्द्रेण-अर्थान्तितन्त्रेषु ते कुजादयो ग्रहाः स्पष्टा न दृष्टा- (न दृश्यन्त्या) स्वस्मत्कारणान् विदुषां (पण्डितानां) मध्ये नैवादरो (अर्थान्तेषां तन्त्राणां विद्वत्समाजे आदरो न) ऽस्तीति ॥४६-४७॥

अब आर्यभट्टादि आचार्यों के दोष को कहते हैं

हि. भा.—आर्यभट्ट-श्रीपिंगल-विष्णुचन्द्र इन आचार्यों के तन्त्रों में मङ्गलादि सब ग्रह युग के आदि में मेपादि से प्रवृत्त नहीं हुये हमलिये वे स्पष्ट नहीं हैं, अर्थान् उनके मत में मङ्गलादि सब ग्रह युगादि में मेपादि में नहीं थे, जिस कारण से श्रीपिंगल-आर्यभट्ट-विष्णुचन्द्र इन आचार्यों के तन्त्रों में वे कुजादि ग्रह स्पष्ट नहीं हैं। उस कारण से पण्डितों के मध्य में उनका आदर नहीं है इति ॥४६-४७॥

अब भीमादि ग्रहों के वक्रारम्भकालिक और मार्गारम्भकालिक शीघ्रकेन्द्रांश को कहते हैं

हि. भा.—१६३°, १४५°, १२५°, १६५°, ११३° इन पठित शीघ्र केन्द्रांशों में
क्रमशः मङ्गलादि ग्रह वक्र होते हैं और इन्हीं को चक्रांग में बदलने से जो शेष रहते हैं
उतने शीघ्र केन्द्रांश में वे अनुवक्र होते हैं, शीघ्रोच्चगति में मन्दस्पष्टगति को बदलने से
शीघ्र केन्द्रगति होती है, पठितकेन्द्रांश से इष्टकेन्द्रांश के अधिक वा घट्य रहने से दोनों के
अन्तर में केन्द्रगति से भाग देने से गतदिन और एष्यदिन होते हैं अर्थात् इष्टदिन से पहले
वा पीछे ग्रह समागत दिनों में ग्रह वक्र या अवक्र हो गये होंगे या होंगे इति ॥४८-४९॥

उपपत्ति

शीउग—स्पकेग=स्पगति, जब शीउग < स्पकेग तब विलोमशोधन से वक्रगति होती है, लेकिन ऐसी स्थिति कहाँ होती है, इसके लिये विचार करते हैं। फलांशखान्दान्तर-

शिज्जिनीघ्नी इत्यादि भास्करोक्त प्रकार से $\frac{\text{फकोज्या. शीकेग}}{\text{शीक}} = \text{स्पकेग}$ इसको देखने से सिद्ध

होता है कि जहाँ पर फलकोटिज्या का परमत्व होगा और शीघ्रकर्ण का परमात्पत्व वहीं पर स्पष्ट केन्द्रगति का परमत्व हो सकता है, नीचस्थान में फलाभाव होने के कारण फलकोटिज्या का परमत्व होता है, तथा शीघ्रकर्ण का परमात्पत्व होता है अतः शीउग < स्पकेग ऐसी स्थिति नीचस्थान ही में हो सकती है, परन्तु वक्रता का आरम्भ तो नीचस्थान से कुछ पहले ही से होगा, कितने शीघ्र केन्द्रांश में वक्रारम्भ होता है उस केन्द्रांश का साधन करते हैं।

कल्पना करते हैं वाक्रारम्भकालिक केन्द्रकोटिज्यामान = य

फलांशखान्तरशिज्जिनीघ्नी इत्यादि भास्करोक्त प्रकार से $\frac{\text{फकोज्या. केग}}{\text{कर्ण}} = \text{स्पकेग}$, नीचस्थान कर्णादि केन्द्र में है, नीचासन्न ही में वक्रारम्भ होता है

अतः $\sqrt{\text{त्रि}^2 + \text{अंफज्या}^2} - २ \text{अंफज्या} \times \text{य} = \text{कर्ण}$; तथा द्राक्केन्द्रकोटिमौव्यन्त्यफलज्या

बुशया इत्यादि सिद्धान्तशिरोमणिस्य संशोधकोक्त प्रकार से $\frac{\text{त्रि}^2 - \text{य} \cdot \text{अंफज्या}}{\text{कर्ण}} = \text{फलकोज्या}$

स्पष्टकेन्द्रगति स्वरूप में फलकोटिज्या और कर्ण का उत्थापन करने से

$\frac{(\text{त्रि}^2 - \text{य} \cdot \text{अंफज्या}) \text{ केग}}{\text{कर्ण}^2} = \frac{(\text{त्रि}^2 - \text{य} \cdot \text{अंफज्या}) \text{ केग}}{\text{त्रि}^2 + \text{अंफज्या}^2 - २ \text{अंफज्या} \cdot \text{य}} = \text{स्पकेग}$, केग = शीघ्र-

केन्द्रगतिः। कर्ण = शीघ्रकर्ण परन्तु वक्रारम्भ में स्पष्टगति = ० इसलिये शीघ्रोच्चगति = स्पष्टकेग। शीउगति = उग।

$\frac{(\text{त्रि}^2 - \text{य} \cdot \text{अंफज्या}) \text{ केग}}{\text{त्रि}^2 + \text{अंफज्या}^2 - २ \text{अंफज्या} \cdot \text{य}} = \text{उग}$, छेदगम करने से।

$\text{त्रि}^2 \text{ केग} - \text{य} \cdot \text{अंफज्या} \cdot \text{केग} = \text{त्रि}^2 \text{ उग} + \text{अंफज्या}^2 \text{ उग} - २ \text{अंफज्या} \cdot \text{य} \cdot \text{उग}$ समशोधन करने से

$\text{त्रि}^2 \text{ उय} - \text{त्रि}^2 \text{ केग} + \text{अंफज्या}^2 \text{ उय} = २ \text{अंफज्या} \cdot \text{य} \cdot \text{उग} - \text{य} \cdot \text{अंफज्या} \cdot \text{केग}$ हस्तपुस्तक को पृच्छ करने से

$$\begin{aligned} \text{त्रि}^{\circ} (\text{उग—केग}) + \text{अ}^{\circ} \text{फज्या}^{\circ} \cdot \text{उग} &= \text{त्रि}^{\circ} \cdot \text{मंस्पग} + \text{अ}^{\circ} \text{फज्या}^{\circ} \cdot \text{उग} \\ &= \text{य} \cdot \text{अ}^{\circ} \text{फज्या} (\text{२ उग—केग}) \\ &= \text{य} \cdot \text{अ}^{\circ} \text{फज्या} (\text{उग} + \text{उग—केग}) \\ &= \text{य} \cdot \text{अ}^{\circ} \text{फज्या} (\text{उग} + \text{मंस्पग}) \end{aligned}$$

अतः $\frac{\text{त्रि}^{\circ} \cdot \text{मंस्पग} + \text{अ}^{\circ} \text{फज्या}^{\circ} \cdot \text{उग}}{\text{अ}^{\circ} \text{फज्या} (\text{उग} + \text{मंस्पग})} = \text{य}$ । यहाँ मध्यमगति और मन्दस्पष्टगति

को तुल्य मान लिया गया है $= \frac{\text{त्रि}^{\circ} \cdot \text{मग} + \text{अ}^{\circ} \text{फज्या}^{\circ} \cdot \text{उग}}{\text{अ}^{\circ} \text{फज्या} (\text{उग} + \text{मग})} = \text{केओज्या}$, इसके चाप में नव-
त्यंश जोड़ने से वक्रारम्भ कालिक शीघ्र केन्द्रांश होता है, इससे “त्रिज्याकृतिः सचरमध्यम-
भुक्तिनिष्पी इत्यादि संस्कृतोपपत्ति में लिखित संशोधकोक्त” सूत्र उपपन्न होता है, लेकिन
यहाँ मन्दस्पष्टगति और मध्यमगति बराबर स्वीकार की गयी है, तदुपनिवृत्ति त्रुटि
इसमें है ।

यहाँ गणित दिखलाते हैं

मङ्गल के वक्रारम्भ कालिक केन्द्रांशानयन के लिये, मङ्गल की अन्त्यफसज्या = ७८,
उच्चगति = ५६' १८", त्रि = १२०, शीघ्रकेन्द्रगति = २८' स्वत्वान्तर से, मध्यमगति
= ३१' १२६" ।

$$\begin{aligned} \text{त्रि}^{\circ} &= (१२०)^{\circ} = १४४००, \text{त्रि}^{\circ} \cdot \text{मग} = १४४०० \times ३१ = ४४६४००, \text{ तथा} \\ \text{अ}^{\circ} \text{फज्या}^{\circ} &= (७८)^{\circ} = ६०८४, \text{ उग} = ५६ \end{aligned}$$

$$\begin{aligned} \text{अ}^{\circ} \text{फज्या}^{\circ} \cdot \text{उग} &= ६०८४ \times ५६ = ३४०६५६, \text{ उग} + \text{मग} \\ &= (३११२६) + (५६१८) = ६०७३४ \end{aligned}$$

$$\text{अ}^{\circ} \text{फज्या} (\text{उग} + \text{मग}) = ७८ (६०७३४) = ७०६४,$$

$$\text{त्रि}^{\circ} \cdot \text{मग} + \text{अ}^{\circ} \text{फज्या}^{\circ} \cdot \text{उग} = ४४६४०० + ३४०६५६ = ८०७०५६,$$

$$\text{अतः} \frac{\text{त्रि}^{\circ} \cdot \text{मग} + \text{अ}^{\circ} \text{फज्या}^{\circ} \cdot \text{उग}}{\text{अ}^{\circ} \text{फज्या} (\text{उग} + \text{मग})} = \frac{८०७०५६}{७०६४} = ११४ = \text{य} = \text{शीघ्रकेओज्या, इसका}$$

चाप = ७८°, नवत्यंश जोड़ने से मङ्गल का वक्रारम्भ कालिक शीघ्रकेन्द्रांश हुआ ७४° + ६०' = १६४°, प्राचार्योक्त मङ्गलशीकेन्द्रांश = १६३°, मङ्गलादि ग्रहों के प्राचार्योक्त वक्रारम्भ कालिक शीघ्रकेन्द्रांश ही को सत्प्राचार्य, श्रीपति, भास्कराचार्य ने अपने-अपने सिद्धान्तग्रन्थ में कहा है । सूर्यसिद्धान्तोक्त ‘मन्वत्पुट्यीकृतां भुक्तिप्रोह्य शीघ्रीज्याभुक्तिज्ज’ इत्यादि शीघ्रवृत्ति-फलानयन में ‘त्रिज्यान्त्यकर्णो’ यहाँ त्रिज्या शब्द से यदि त्रिज्या ही का ग्रहण किया जाय तब उनके पठित केन्द्रांश नहीं मिलते हैं जैसे सूर्यसिद्धान्तोक्तप्रकार से केय. त्रि $\frac{\text{उग}}{\text{मग}}$ = उग, ∴ केय. त्रि = उग. क । उगुं = क

वर्ग करने से केग^३ त्रि^३ = उग^३ क^३ = उग^३ (त्रि^३ + अंफज्या^३ - २ केकोज्या.

$$\text{अंफज्या} = \text{त्रि}^2 (\text{उग}^2 - २ \text{ उग} \cdot \text{मग} + \text{मग}^2)$$

$$= \text{उग}^3 \cdot \text{त्रि}^2 - \text{उग}^3 \cdot \text{अंफज्या}^2 - \text{उग}^3 \cdot २ \text{ केकोज्या}.$$

$$\text{अंफज्या} = \text{त्रि}^2 \cdot \text{उग}^2 - २ \text{ उग} \cdot \text{मग} \cdot \text{त्रि}^2 + \text{त्रि}^2 \cdot \text{मग}^2$$

समशोधन से उग^३ अंफज्या^३ - उग^३ २ केकोज्या अंफज्या = त्रि^३ मग^३ - २ उग.

मग. त्रि^३ पुनः समशोधन से

$$\text{उग}^2 \cdot २ \text{ केकोज्या} \cdot \text{अंफज्या} = \text{उग}^3 \cdot \text{अंफज्या}^2 + २ \text{ उग} \cdot \text{मग} \cdot \text{त्रि}^2 - \text{त्रि}^2 \cdot \text{मग}^2$$

$$= \text{उग}^3 \cdot \text{अंफज्या}^2 + \text{त्रि}^2 \cdot \text{मग} (२ \text{ उग} - \text{मग})$$

$$\text{अतः} \frac{\text{उग}^3 \cdot \text{अंफज्या}^2 + \text{त्रि}^2 \cdot \text{मग} (२ \text{ उग} - \text{मग})}{२ \text{ उग}^3 \cdot \text{अंफज्या}}$$

$$= \frac{\text{उग}^3 \cdot \text{अंफज्या}^2 + \text{त्रि}^2 (\text{उग}^2 - \text{केग}^2)}{२ \text{ उग}^3 - \text{अंफज्या}} = \text{केकोज्या},$$

इसके चाप में नवत्यंश जोड़ने से कमलाकरमतानुसार वक्रारम्भ कालिक शीघ्र-केन्द्रांश होता है।

प्रतीत्यर्थगणित दिखलाते हैं

$$\text{जैसे मङ्गल की प्रत्यफलज्या} = ७८, \text{ मध्यमगति} = ३१' १२'',$$

$$\text{उच्चगति} = ५६' १८'', \text{ त्रिज्या} = १२०, \text{ शीघ्रकेगति} = २८'$$

$$\text{अंफज्या}^2 = (७८)^2 = ६०८४, \text{ उग}^2 = ३४८१, \text{ उग}^3 \cdot \text{अंफज्या}^2$$

$$= ६०८४ \times ३४८१ = २११७८४०४१$$

$$\text{केग}^2 = २८^2 = ७८४, \text{ उग}^2 - \text{केग}^2 = ३४८१ - ७८४ = २६९७,$$

$$\text{त्रि}^2 = (१२०)^2 = १४४००$$

$$\text{त्रि}^2 (\text{उग}^2 - \text{केग}^2) = २६९७ \times १४४०० = ३८८३६८००$$

$$\text{उग}^3 \cdot \text{अंफज्या}^2 + \text{त्रि}^2 (\text{उग}^2 - \text{केग}^2) = २११७८४०४ + ३८८३६८००$$

$$= ६००१५२०४, २\text{उग}^3 = ६९६२$$

$$२\text{उग}^3 \cdot \text{अंफज्या} = ६९६२ \times ७८ = ५४३०३६$$

$$\therefore \frac{\text{उग}^3 \cdot \text{अंफज्या}^2 + \text{त्रि}^2 (\text{उग}^2 - \text{केग}^2)}{२\text{उग}^3 \cdot \text{अंफज्या}} = \frac{६००१५२०४}{५४३०३६} = १११$$

इसका चाप = ६८° नवत्यंश जोड़ने से ६८° + ६०° = १२८° = कमलाकरमतानुसार वक्रारम्भकालिक मङ्गलशीकेन्द्रांश यह आचार्योक्तशीघ्रकेन्द्रांश १६३° से बहुत अन्तरित

(फरक) है इसलिये विज्या गण्ड से विज्या का ग्रहण करना ठीक नहीं है, विज्या गण्ड में शीघ्रफलकोविज्या का ग्रहण करना चाहिये। यह सूर्यमिहान्त की एडिथेनकास टीका में रङ्गनाथ का कहना बहुत ठीक है, क्योंकि फलकोविज्या के सम्बन्ध में ही गण्ड में लगे हुये मङ्गल के शीघ्रकेन्द्रांश = १६४, पाठपठितकेन्द्रांश १६३ के साथ अन्तर = १ कल्पनाकर ने व्यय ही रङ्गनाथ मत का खण्डन किया है, इस विषय को विवेक लोग विचारें। नीच स्थान से जितने अन्तर में वक्रारम्भ होता है उसके विरुद्ध दिशा में उतने ही अन्तर में वक्रत्याग होता है, इसलिये वक्रारम्भकालिककेन्द्रांश को भगगांश ३९० में घटाते से मागीरम्भ (वक्रत्याग कालिक) कालिक केन्द्रांश होता है। ग्रहों की वक्रता या अवक्रता इष्टदिन से कितने पहले हो चुकी है या होगी इसके लिये इष्टशीघ्रकेन्द्रांश में वक्रावक्रपठितकेन्द्रांशों को घटाकर शेष से अनुपात करने हैं, यदि केन्द्रगति में एक दिन पाते हैं तो शेष में क्या हमने लब्ध दिनों में ग्रह वक्रत्व या अवक्रत्व में प्राप्त हो चुके हैं या होंगे इति ॥४८-४९॥

अत्रोपपत्तिः

वक्रातिवक्रादीनां नामानि संहिताकारोक्तवज्ज्ञेयानि शिष्यधीवृद्धिदे लल्लाचार्यैरेवमेव कथ्यते यथा—

“मध्यस्फुटान्तरदलेन चलात् समेतान्मध्ये,
स्फुटात् समधिके सति चान्यथोनात् ।
स्फुटं त्यजेत् कृतषडष्टसु तत्र शेषु,
वक्रातिवक्रकुटिला गतयो भवन्ति” ॥

सिद्धान्तशेखरे “शीघ्रोच्चात् स्पष्टमध्यग्रहविवरदलं मध्यमे शोध्यमूने देयं स्पष्टादमूने स्फुटसचरमन्त्रप्रोज्ञस्य तत्रावशेषे । वक्रं विध्यज्जिराशिष्वथ ऋतुषु ६ महावक्रमष्टासु ८ वक्रत्यागं कैन्नुभुक्त्या पुनरपि हरस्व यामयेवान्यहानि” श्रीपत्युक्तमिदं ब्रह्मगुप्तोक्तसत्त्वाचार्योक्तयोरनुसम्भवेन, नतैष्यदिनानयनं सुगममेवेति ॥५०-५१॥

ज्ञान वक्र-अतिवक्र और अनुवक्र की परिचयना कहते हैं

हि. भा.—शीघ्रोच्च में स्पष्टग्रह को पढ़ाने से जो शेष रहे उसमें स्पष्टग्रह से बलफल संस्कृत ग्रह के अधिक रहने से मन्दफलस्फुटग्रह और स्फुटग्रह के अन्तरार्ध को घट करके स्फुटग्रह से बलफल संस्कृतग्रह के कल (कम्) रहते से उस शेष में मध्यस्फुटान्तरार्ध को गणना करना, इस तरह संस्कृत शेष चार राशि में देखा जाय तो वक्र समझना चाहिये, व. राशि में अतिवक्र और भाठ राशि में अनुवक्र समझना चाहिये, वक्रज्ञान के

लिये इष्टदिन में 'शीघ्रात् स्फुटग्रहोनात्' इत्यादि विधि से मध्यस्फुटान्तरार्ध संस्कृत शेष चार राशि से अल्प हो तो मध्यस्फुटान्तरार्ध संस्कृत शेष और चार राशि की अन्तरकला अप्राप्तकला (एष्यकला) होती है, यदि मध्यस्फुटान्तरार्ध संस्कृत शेष चार राशि से अधिक हो तो दोनों की अन्तरकला प्रतीतकला (गतकला) होती है, गतकला और एष्यकला को गतदिन और एष्यदिन के 'शीघ्रात्स्फुटोनात्' इत्यादि विधि से लाये हुये संस्कृत शेष द्वय के अन्तर तुल्य गति से भाग देने से गतदिन और एष्यदिन होता है ॥५०-५१॥

उपपत्ति

वक्र-अतिवक्र-अनुवक्र इन सबों के नाम फनार्थ संहिताकार ने जो रखे हैं उसी तरह समझने चाहियें, शिष्यधीवृद्धि में लल्लाचार्य आचार्योक्तानुसार ही कहते हैं जैसे 'मध्य-स्फुटान्तरदलेन चलात्' इत्यादि' संस्कृतोपपत्ति में लिखा गया है, सिद्धान्तोत्तर में शीघ्रो-च्चात् स्पष्टमध्यग्रहविवरदनं' इत्यादि' संस्कृतोपपत्तिमें लिखित पद्य से श्रीपति 'ब्रह्मगुप्तोक्त और लल्लाचार्योक्त के' अनुरूप ही कहते हैं । गतंष्यदिनानयन सुगम ही है इति ॥५०-५१॥

भास्करेण चाऽऽचार्योक्तानुरूपमेव सर्वं कथितमिति ॥५२-५३॥

अब कुजादिग्रहों के उदयकेन्द्रांश और अस्तकेन्द्रांश को कहते हैं

हि. भा.—यज्ञल, बुध, और शनैश्चर क्रमशः २८, १४, १७ इन केन्द्रांशों में पूर्व दिशा में उदित होते हैं । इन केन्द्रांशों को ३६० में घटाने से जो रहता है उन केन्द्रांशों में पश्चिम दिशा में वे अस्त होते हैं । बुध, और शुक्र क्रमशः ५०, २४ केन्द्रांशों में पश्चिम दिशा में उदित होते हैं तथा १५५, १७७ इन केन्द्रांशों में पश्चिम दिशा में अस्त होते हैं ।

बुध के पञ्चादय केन्द्रांश = ५०, इसको ३६०° चक्रांश में घटाने से शेष ३१० इतने केन्द्रांश में पूर्व दिशा में अस्त होते हैं। शुक्र के पञ्चमोदयकेन्द्रांश = २४, चक्रांश ३६० में घटाने से शेष ३३६ इतने केन्द्रांश में पूर्व दिशा में अस्त होते हैं। बुध के पञ्चादय केन्द्रांश १५५ इनको चक्रांश में घटाने से शेष २०५ इन केन्द्रांशों में पूर्व दिशा में उदय होते हैं। शुक्र के पञ्चादयकेन्द्रांश १७७ इनको चक्रांश में घटाने से शेष १८३ इन केन्द्रांशों में पूर्व दिशा में उदित होते हैं इति ॥५२-५३॥

उपपत्तिः

कुज-गुरु और शनैश्चर इन सबों का रवि ही शीघ्रोच्च है, शीघ्रोच्च स्थान में उन सबों का परमास्त होता है, उन सबों से रवि के शीघ्रगतित्व के कारण रवि प्रागे चला जाता है, जब कालांश तुल्य अन्तर होता है तो रवि के सानिध्यवश से रात्रिशेष में उन सबों का उदय होता है, इसलिये कालांशतुल्य स्पष्टकेन्द्रांश में जो फलचाप होता है उसको कालांश में जोड़ने से उनके उदय केन्द्रांश होते हैं। जैसे यदि त्रिज्या में कालांश तुल्य स्पष्टकेन्द्रांश की ज्या पाते हैं तो अन्त्यफलज्या में क्या इस अनुपात से कालांश तुल्यस्पष्ट केन्द्रांशज्या

जनित फलज्या प्राप्ती है $\frac{\text{अंफज्या.कालांशज्या}}{\text{त्रि.}}$ इसके चाप में कालांश जोड़ने से कुज, गुरु और

शनैश्चर इन सबों के उदय केन्द्रांश होते हैं, इससे म. म. पण्डित सुवाकर द्विवेदी का सूत्र उपपन्न हुआ, “कालांशजीवाज्ज्यफलज्ययाध्नी त्रिज्ययाप्ता” इत्यादि संस्कृतोपपत्ति में लिखित सूत्र को देखिये। प्रतीत्यर्थमणित देखिये, जैसे कुज की अन्त्यफलज्या = ८१, कालांश = १७,

कालांशज्या = ३५, त्रिज्या = १२०, तब उपरिलिखित सूत्रानुसार $\frac{\text{कालांशज्या.अंफज्या}}{\text{त्रि.}}$

$$= \frac{३५ \times ८१}{१२०} = \text{फलज्या, इसका चाप} = ११^\circ \text{ कालांश जोड़ने से } ११^\circ + १७^\circ = २८^\circ =$$

कुज के उदय केन्द्रांश, इसी तरह गुरु और शनैश्चर का उदय केन्द्रांश ज्ञाना चाहिये। बुध और शुक्र के बराबर ही मध्यमरवि होते हैं, इसके बराबर ही मन्दस्पष्ट बुध या शुक्र को मानकर स्पष्ट बुध या स्पष्ट शुक्र के साथ कालांश तुल्य अन्तर पर पश्चिम दिशा में

उनके उदय को देखते हैं, तब $\frac{\text{कालांशज्या.त्रि.}}{\text{अंफज्या}} = \text{स्पकेज्या, इसके चाप में कालांश जोड़ने}$

से प्रथमपद में पञ्चमोदयकेन्द्रांश होता है, द्वितीयपद में नक्षत्रा को प्राप्त कर रवि से अल्पगतित्व के कारण वहीं पर वे दोनों (बुध, शुक्र) अस्त होते हैं, तृतीयपद में उन दोनों का फिर उदय होता है, नीच स्थान में उन दोनों का परमास्त होने से रात्रि शेष में पूर्व दिशा में वह उदय देखा जाता है, चतुर्थपद में उन दोनों के कालांशान्तर पर रहने के कारण वे वहीं पर अस्त होते हैं इसलिये पूर्वोक्त केन्द्रांश = चाप—कालांश + १८० = चा

+(१८०—कालांश) इससे संस्कृतोपपत्ति में लिखित 'जशुक्रयोस्तु त्रिमशिञ्जिनीघ्नी इत्यादि' म. म. सुधाकर द्विवेदी का सूत्र उपपन्न होता है, अब प्रतीति के लिये गणित दिखलाते हैं ।

बुध की अन्त्यफलज्या = ४४, पश्चिमोदयकालांश = १३, कालांशज्या = २७,

त्रिज्या = १२०, तब पूर्वलिखितसूत्रानुसार $\frac{\text{कालांशज्या.त्रि}}{\text{अंशज्या}} = \frac{२७ \times १२०}{४४} = ७३$, इसका

चाप = ३७° कालांश जोड़ने से ३७° + १३° = ५०° = पश्चिमोदयकेन्द्रांश पूर्वोदयकालांश = १२, तब पूर्वोदयकेन्द्रांश = (१८० = कालांश) + चाप = २७ + १६८ = २०५, इसी तरह शुक्र का भी केन्द्रांश लाना चाहिये । सिद्धान्तशेखर में श्रीपति 'वस्वस्विभिर्युगकुभिः इत्यादि' संस्कृतोपपत्ति में लिखित सूत्र से और सिद्धान्तशिरोमणि में भास्कराचार्य ने 'प्राच्यामुदेति क्षितिजोऽष्टदस्रैः इत्यादि' संस्कृतोपपत्ति में लिखित सूत्रों से आचार्योक्तानुरूप ही सब कुछ कहा है इति ॥५२-५३॥

वि. भा.—पूर्व ये कुजादिग्रहाः साधितास्ते द्युगत्रिदन्त्योन्मत्तदिनार्धे गच्छन् वा गणितागताः स्पष्टाः स्युः। अर्थात्तेषु चरसंस्काराभावः। रव्युदयान्तमययोः (यदि रव्युदयेऽन्तमये वा) साधिताम्यदा रविचरार्थान् (रविचरफलसंस्कारान्) स्वदेशे रव्युदयेऽन्तमये वा ते स्पष्टा भवन्ति, अनीताद् ग्रहान् (गतदिनोद्भव्याद् ग्रहात्) एष्ये (आगामिदिनोद्भवे ग्रहे) अधिके सति अवक्रिनः (मार्गः) हीने (गतदिनोद्भवग्रहादागामिदिनोद्भवग्रहे न्यून) सति वक्रितो ज्ञेयः उपपत्तिर्गमि भाष्येनैव स्पष्टेति ॥१५४॥

अब स्वदेश में कैसे स्पष्ट ग्रह होते हैं इसके लिये कहते हैं

हि. भा.—पहले जो कुजादि ग्रहों का साधन किया गया है वे (साधितग्रह) दिनार्धकाल में या रात्र्यर्ध में स्पष्ट होने हैं। क्योंकि उनमें चर संस्कार नहीं किया गया है, यदि रवि के उदयकाल में या अस्तकाल में साधित ग्रह हों तो उनमें रविचरफल संस्कार करने से स्वदेश में रवि के उदयकाल या अस्तकाल में वे स्पष्ट होते हैं। यदि गतदिन के ग्रह से अग्रिम दिन का ग्रह अधिक हो तो ग्रह को मार्गी समझना चाहिये यदि गतदिन के ग्रह से अग्रिम दिन का ग्रह हीन हो तो ग्रह को वक्र समझना चाहिये। इसकी उपपत्ति भी साफ ही है ॥१५४॥

अथ पञ्चज्यानयन को कहते हैं

हि.भा. —रवि भुजज्या को जिनज्या (परम क्रान्तिज्या) से गुणा कर त्रिज्या से भाग देने
से लब्धि रवि की दृष्ट क्रान्तिज्या होती है नाङ्गी वृत्त से सूर्य के उत्तर रहने से उसकी (क्रान्ति-
ज्या) की दिशा उत्तर होती है, और नाङ्गीवृत्त से सूर्य के दक्षिण रहने से उसकी दिशा दक्षिण
होती है । त्रिज्यावर्ग में से दृष्ट क्रान्तिज्या वर्ग को घटाकर शेष का मूल ग्रहोरात्र वृत्त का
व्यासार्ध (द्युज्या) होता है, इसकी दिशा भी क्रान्तिज्या की दिशा की तरह होती है, क्रान्ति-
ज्या को पनभा से गुणा कर द्वादश १२ से भाग देने से क्षितिज्या (कुज्या) होती है, इसको
पृथक् स्थापन करना, उस कुज्या को त्रिज्या से गुणा कर द्युज्या से भाग देने से क्षयवृद्धिज्या
(चरज्या) होती है, इसका चाप चर प्राण (चरामु) होता है, चरामु को छः से भाग देने से
विनाङ्गी (पल) होती है, नाङ्गी (दण्ड) को ६० से भाग देने से विनाङ्गिका (पल) होती है
इति ॥ ५५-५६-५७-५८ ॥

उपपत्ति ।

क्रान्तिवृत्त में जहां रवि है उनके ऊपर ध्रुवप्रोतवृत्त कर देना, नाङ्गीवृत्त और क्रान्तिवृत्त
के सम्पात (गोलसन्धि) से नवत्यंश व्यासार्ध से वृत्त (अयनप्रोतवृत्त) करना, तब दो चापीय
जात्य त्रिभुज बनता है, गोल सन्धि से अयन प्रोतवृत्त क्रान्तिवृत्त के सम्पात पर्यन्त क्रान्तिवृत्त
में नवत्यंश एक भुज, गोल सन्धि से अयन प्रोत वृत्त नाङ्गीवृत्त के सम्पात पर्यन्त नाङ्गीवृत्त में
नवत्यंश द्वितीयभुज, नाङ्गीवृत्त और क्रान्तिवृत्त के अन्तर्गत अयन प्रोत वृत्तीय चाप (परम
क्रान्ति) तृतीय भुज; इन तीनों भुजों से एक त्रिभुज बना, तथा गोलसन्धि से रविपर्यन्त
क्रान्तिवृत्त में रविभुजांश कर्ण एक भुज, रवि से रविगत ध्रुव प्रोतवृत्त के नाङ्गीवृत्त सम्पात

पर्यन्त ध्रुव प्रोतवृत्त में इष्ट क्रान्ति द्वितीय भुज गोल मन्धि से ध्रुव प्रोतवृत्त नाड़ीवृत्त के सम्मान पर्यन्त नाड़ी वृत्त में विषुवांश कोटि तृतीय भुज, इन तीनों भुजों से द्वितीय त्रिभुज हुआ, इन दोनों चापीय त्रिभुजों का ज्याक्षेत्र सजातीय होता है इसलिए पहले लघु त्रिभुज (द्वितीय त्रिभुज) का ज्याक्षेत्र करने हैं, गोल केन्द्र (भूकेन्द्र) से गोलसन्धिगत रेखा कर देना उसके ऊपर रवि केन्द्र से लम्ब रेखा रवि भुजज्या होती है, भूकेन्द्र से नाड़ीवृत्त ध्रुव प्रोत वृत्त सम्मानगत रेखा करना, उस के ऊपर रवि केन्द्र से लम्ब रेखा क्रान्तिज्या (क्रान्ति चाप की ज्या) होती है, इन दोनों (भुजज्या और क्रान्तिज्या) की मूल गत रेखा कर देना यह विषुवांश चाप की ज्या नहीं है, भुजज्या, क्रान्तिज्या, तन्मूलगत रेखाओं से जो त्रिभुज होता है, वही उक्त चापीय जात्य त्रिभुज का ज्याक्षेत्र होता है नाड़ीवृत्त धरातल के ऊपर क्रान्तिज्या लम्ब है, तथा मूलगत रेखा नाड़ीवृत्त धरातलगत है इसलिए मूलगत रेखा के ऊपर भी क्रान्तिज्या लम्ब होती है (धरातल के ऊपर रेखा लम्ब की परिभाषा से) इसलिये उक्त त्रिभुज; जात्य त्रिभुज हुआ, नाड़ी वृत्त और ध्रुव प्रोत वृत्त के सम्पात से गोलसन्धिगत रेखा के ऊपर लम्ब रेखा विषुवांश चाप की ज्या है, मूलगत रेखा गोल मन्धिगत रेखा के ऊपर लम्ब है, गोल केन्द्र से नाड़ीवृत्त ध्रुव प्रोत वृत्त सम्पातगत त्रिज्या कर्ण, विषुवांशज्या भुज, और विषुवांशज्या मूल से गोल केन्द्र पर्यन्त विषुवांश कोटिज्या कोटि, इन तीनों भुजों से एक त्रिभुज हुआ तथा गोल केन्द्र से क्रान्तिज्या मूल पर्यन्त क्रान्ति की उत्क्रमज्योन त्रिज्या (क्रान्तिकोटिज्या = बुज्या) कर्ण, मूलगत रेखा भुज, और गोल केन्द्र से भुजज्या मूल पर्यन्त कोटि, इन तीनों भुजों से द्वितीय त्रिभुज हुआ, ये दोनों त्रिभुज सजातीय हैं इसलिए अनुपात करते हैं यदि त्रिज्या में विषुवांशज्या पाते हैं तो बुज्या में क्या इससे मूलगत रेखा आती है इससे सिद्ध होता है कि किसी भी चापीय जात्य त्रिभुज के ज्याक्षेत्र में कर्णचाप ज्या वास्तविक होती है, भुजचाप और कोटिचाप में किसी एक चाप की ज्या वास्तविक ही होती है, अन्य चाप की ज्या वास्तव नहीं होती है अर्थात् जिस चाप की ज्या वास्तविक होती है उसी के कोटिव्यासार्ध वृत्त में परिणत होती है, जैसे उपरिलिखित चापीय जात्य त्रिभुज के ज्याक्षेत्र में भुजांशकर्ण और क्रान्तिभुज की ज्याए वास्तविक हैं, कोटिचाप विषुवांश की ज्या वास्तव नहीं है किन्तु भुज (क्रान्ति) कोटिव्यासार्धवृत्त (बुज्या व्यासार्ध वृत्त) में परिणत होकर मूलगत रेखा (कमलाकरोक्त व्यसोदय लब्धज्या) होती है, नवत्यंश, नवत्यंश और जिनांश इन भुजों से उत्पन्न त्रिभुज का ज्याक्षेत्र (त्रिज्या कर्ण, जिनज्या भुज, जिनांश कोटिज्या = पर मात्पबुज्या, कोटि से उत्पन्न त्रिभुज) पूर्वोक्त त्रिभुज (भुजज्या, क्रान्तिज्या, मूलगत रेखाओं से उत्पन्न त्रिभुज) का सजातीय है इसलिये अनुपात करते हैं यदि त्रिज्या में जिनज्या (परम क्रान्तिज्या) पाते हैं तो रविभुजज्या में क्या इस अनुपात से इष्टक्रान्तिज्या आती है, जिज्या. भुज्या

त्रि = इकांज्या, त्रिज्या कर्ण, क्रान्तिज्या भुज, क्रान्तिकोटिज्या

(बुज्या) कोटि इन भुजों से उत्पन्न त्रिभुज में $\sqrt{\text{त्रि}^2 - \text{कांज्या}^2} = \text{बुज्या}$, अत्राकर्ण, क्रान्तिज्या कोटि, बुज्या भुज इन भुजों से उत्पन्न एक त्रिभुज, तथा द्वादश कोटि पलभा भुज, पलकर्ण

करा, इन भुजों से उत्पन्न द्वितीय त्रिभुज, दोनों अक्षक्षेत्र है इसलिये सजातीय होने के कारण अनुपात करते हैं $\frac{\text{पभा. क्रांज्या}}{१२} = \text{कुज्या}$, क्षितिजाहोरात्र वृत्त के सम्पातगत ध्रुवप्रोत वृत्त में

ध्रुव से नाड़ी वृत्त पर्यन्त नवत्यंश, ध्रुव से पूर्वस्वस्तिक पर्यन्त उन्मण्डल में नवत्यंश, पूर्वस्वस्तिक से ध्रुवप्रोत वृत्त नाड़ीवृत्त के सम्पात पर्यन्त नाड़ीवृत्त में चरांश, इन भुजों से उत्पन्न एक त्रिभुज, तथा ध्रुव से क्षितिजाहोरात्र वृत्त के सम्पात पर्यन्त ध्रुव प्रोत वृत्त में द्युज्या चाप एक भुज, ध्रुव से उन्मण्डल और अहोरात्र वृत्त के सम्पात पर्यन्त उन्मण्डल में द्युज्याचाप द्वितीय भुज, अहोरात्र वृत्त में क्षितिज वृत्त और उन्मण्डल के अन्तर्गत चाप तृतीय भुज, इन भुजों से उत्पन्न द्वितीय त्रिभुज का ज्याक्षेत्र प्रथम त्रिभुज के ज्याक्षेत्र का सजातीय है इसलिये अनुपात करते हैं। यदि द्युज्या में कुज्या पाते हैं तो त्रिज्या में क्या इससे चरज्या आती है, $\frac{\text{कुज्या. त्रि}}{\text{द्यु}} = \text{चरज्या}$, इसका चाप = चरामु, यहां रविभुजज्या, क्रान्तिज्या, द्युज्या, कुज्या,

चरज्या, यह पञ्चज्यानयन किया गया है, आचार्य के मत में अयनांशाभाव है, इसलिए यथागत रवि ही साधित रवि होता है; भास्कराचार्य ने सायन रवि की भुजज्या का साधन किया है वही उन के मत में विशेषता है, इति ॥ ५५-५६-५७-५८ ॥

इदानीं चरकर्महि

चरदलघटिका गुणिता भुक्तिः षष्ट्याहृता कलाद्याप्तम् ।

ऋणमुदयेऽस्तमये धनमुत्तरगोलेऽन्यथा याम्ये ॥ ५९ ॥

वा. भा.—चरदलघटिकाभिरिष्टग्रहभुक्तिं संगुणय्य षष्ट्या विभजेत् फलं लिप्तादि तदुत्तरगोलस्थे रवावौदयिके ग्रहे ऋणमस्तमयिके धनं दक्षिणगोलस्थे च रवावौदयिके धनमस्तमयिके ऋणमेवं स्वदेशार्कौदयकाले ऽस्तमयकाले वा ग्रहो भवति अस्तमयिको यो ऽर्धभुकृत्याकृत् तत्र च काले चरदलघटिकातुल्यादि तस्य घटिका गता भवति अतो रव्युदयकालिको ग्रहश्चरदलघटिका फलेनोपचितौदयिको भवति, फलं च त्रैराशिकेन यदि घटिकानां षष्ट्या ग्रहभुक्तितुल्यलिप्ता भवन्ति । तच्चरदलघटिकाभिः किमिति - लिप्तादिफलं पश्चादप्युन्मंडलकालिका एवं तत्र च काले दिनशेषघटिकाश्चरदलतुल्या भवन्ति । अतश्चरार्धघटिका फलेनोपचितो ग्रहो रव्यौदयिको भवति । याम्ये गोलार्धे वैपरीत्ये तत् क्षितिजमंडलादधः स्थितत्वादुन्मंडलस्य यथास्थितं सर्वं गोले प्रदर्शयेत् । स्वदेशाक्षाग्रयोगेन विन्यसेत् ।

अन्यथा (विपरीतं) अर्थादुत्तरगोले सहितं दक्षिणगोले रहित कार्यमिति ॥ ५९ ॥

अत्रोपपत्तिः

अहर्गणेन साधिता ग्रहा लंकाक्षितिजोदयकालिका भवन्ति, ते देशान्तरफलेन संस्कृतास्तदोन्मण्डलकालिका भवन्ति, परन्त्वपेक्षितास्तु स्वक्षितिजोदयकालिकाः, उन्मण्डलस्वक्षितिजयोरन्तरे चरार्धम् तेनानुपातो यदि पश्चिमघटीभिर्ग्रहगतिवला लभ्यन्ते तदा चरार्धघटीभिः किं समागच्छन्ति चरार्धघट्यन्तर्गतग्रहगतिकलाः, आभिः कलाभिरुत्तरगोल उन्मण्डलकालिको ग्रहो हीन (उन्मण्डलात् स्वक्षितिजस्याधो विद्यमानत्वात्) सदा स्वक्षितिजोदयकालिकग्रहो भवेत् । दक्षिणगोले स्वक्षितिजस्योन्मण्डलादुपरि स्थितत्वात् आभिः कलाभिः सहितो ग्रहः (उन्मण्डलकालिकः) स्वक्षितिजोदयकालिको भवेत् । परं चरार्धघट्यन्तर्गतग्रहगतिग्रहणमन्तरैवैवं भवितुमर्हति तद्गतिग्रहणन्वावश्यकमत आचार्योक्तचरफलसंस्कारो न शोभनः, असकृत्कर्मणाऽत्र ग्रह औदयिको भवितुमर्हतीति, सकृत्कर्मणापि पूर्वं वास्तवोदयान्तरसाधने एकामुजेन गतिमङ्गीकृतैकलिप्तोत्पन्नास्वित्याद्युपपत्तौ भाज्यस्थाने यदि प्राचीन चरफलं गृह्येत तदा वास्तवं चरफलं समागच्छेदेवेति ॥ ५९ ॥

अब चरकर्म को कहते हैं ।

हि. भा.—ग्रहगति को चरखण्ड घटी से गुणा कर साठ से भाग देने से जो कलादि फल हो उसको उत्तर गोल में उदयकाल में ग्रह में ऋण करना, दक्षिण गोल में धन करना, अस्तकाल में विपरीत (उल्टा) अर्थात् उत्तर गोल में ग्रह में धन करना और दक्षिण गोल में ऋण करना चाहिये इति ॥५९॥

उपपत्ति

ग्रहगण से साधित ग्रह लङ्काक्षितिजोदय कालिक होते हैं, उन में देशान्तर फल को संस्कार करने से उन्मण्डल कालिक होते हैं लेकिन अपेक्षित है स्वक्षितिजोदयकालिक ग्रह, उन्मण्डल और स्वक्षितिज के अन्तर में चरार्ध है, इसलिये अनुपात करते हैं, यदि साठ ६० घटी में ग्रहगति कला पाते हैं तो चरार्ध घटी में क्या इससे चरार्ध घटी सम्बन्धिनी ग्रहगति कला आती है । इनको उत्तर गोल में उन्मण्डल से अपने क्षितिज को नीचा रहने के कारण उन्मण्डल कालिक ग्रह में से घटाने से स्वक्षितिजोदय कालिक ग्रह होते हैं । दक्षिण गोल में उन्मण्डल से अपने क्षितिज के ऊपर रहने के कारण पूर्वागत चरार्ध घटी सम्बन्धिनी ग्रहगति कला को उन्मण्डल कालिक ग्रह में जोड़ने से स्वक्षितिजोदय कालिक ग्रह होते हैं । लेकिन चरार्ध घट्यन्तर्गत जो कुछ ग्रहगति होगी उसका ग्रहण आचार्य ने नहीं किया है, लेकिन उसका ग्रहण करना आवश्यक है इसलिए आचार्योक्त चरफलसंस्कार ठीक नहीं है, असकृत्कर्म से यहां

औदयिक ग्रह हो सकने हैं, मङ्गलप्रकार में भी पहले वास्तवोदयान्तर माघत में एकानुजेत गति-संगुणितैक लिप्तोन्पन्नामु इत्यादि की उपपत्ति में भाज्यम्यात में प्राचीनोक्त चरफल ग्रहण में वास्तव चरफल आता है, मिद्धान्तशेखर में 'ग्रहगति चर खण्ड प्राणपिण्डाभिधानात्' इत्यादि श्रीपति का प्रकार आचार्योक्तानुरूप ही है, भास्कराचार्य भी "चरश्चनुक्तिर्द्विदशाम् भक्तः" इत्यादि से उसी विषय को कहते हैं. चरफल संस्कार किनी भी प्राचीनाचार्य का टीक नहीं है यह उपर्युक्त युक्ति से स्पष्ट है इति ॥५६॥

इदानीं दिनरात्रिमानमाह

दिनमानरात्रिघटिकाश्चरार्धघटिकाभिरुत्तरे गोले ।

पञ्चदश युक्तहीना याम्ये हीनाधिका द्विगुणाः ॥ ६० ॥

वा. भा.—स्पष्टार्थाऽत्र वासना, इष्टदिने स्वाहोरात्रवृत्तं घटिकांकितं कृत्वा सभागैस्तत्रैकस्मिन्वृत्तपादे पंचदशघटिका भवन्ति । याम्योत्तरमंडलस्वाहोरात्र-वृत्तसंपातादुभयतोपि प्राक्परयोरुन्मंडलेन सह त्वहोरात्रसंपातौ । पंचदशघटिका-वच्छिन्नौ नवस्वदेशोन्मंडलोदयास्तमयौ क्षितिजस्यान्यत्वात् उत्तरगोलेऽर्धक्षितिजं क्षितिजाच्च रविमुद्यन्तं पश्यति भूस्थः तस्मात्प्राक्प्रदर्शितचरदलघटिकाभिरधिकाः पंचदशघटिका दिनार्धं भवति । पश्चादस्तक्षितिजमेवास्तमेति तस्मात्ततोपि स्वाहो-रात्र खंडलेन चरदलाख्येन पंचदशघटिका उपचिता सत्यो दिनार्धत्वं भजन्ते अतो द्विगुणं दिनदलमेव दिनप्रमाणं शेषा घटिकास्वाहोरात्रवृत्ते एभिःप्रमाणसु तच्चोभयश्च तच्चरदलेनखंडित मतो द्विगुणं पंचचरदलं त्रिंशतो विशोध्य रात्रिः प्रमाणमुत्तरगोले याम्ये सर्वं वैपरीत्येन योजयेत् । निरक्षदेशे पुनः क्षितिजोन्मंडल-योरेकत्वाच्चरदलाभाव एवमुत्तरगोले तावद्दिनार्धमुपचीयते । यावत् पंचदश घटिकाश्चरार्धं भवति, तत्ररात्रेरभावः तत्र दिने एतच्च तत्र सम्भवति, यत्र षट्षष्टि रक्षांशाः पुरतः परतश्च तावदुपचीयते यावन्मेरौ । तत्र मेरौ षड्भिर्मा-सैर्दिनं षड्भी रात्रिः एवं निरक्षदक्षिणेनापि योज्यम् एतच्च त्रिप्रश्नोत्तराध्याये वक्षत्याचार्यः, एवमपि तत्रैव व्यावर्णयिष्यामः ।

वि. भा.—उत्तरे गोले पञ्चदशनाडिकाश्चरार्धघटीभिर्युक्ता हीनाश्च द्विगुणा-स्तथा याम्ये (दक्षिणे गोले) पञ्चदश घटिकाश्चरार्धघटीभिर्हीना युक्ताश्च द्विगुणा-स्तदा दिनमानघट्यो रात्रिमानघट्यो भवन्तीति ॥ ६० ॥

अत्रोपपत्तिः

उन्मण्डलयाम्योत्तरवृत्तयोरन्तरे पञ्चदश घट्यः । स्वक्षितिजोन्मण्डलयो-रन्तरे चरार्धम् । उत्तरगोले स्वक्षितिजादुन्मण्डलस्योपरिस्थित्वाच्चरार्धघटीयुक्ताः

पञ्चदशनाड्यो दिनार्धप्रमाण भवेत् । दक्षिणगोले तु स्वक्षितिजादुन्मण्डलस्याधः स्थितत्वाच्चरघटीहीनाः पञ्चदशघट्यो दिनार्धप्रमाणम् । उभयगोलीय दिनार्धमानं त्रिमतः शोध्यं तदोभयगोलीयरात्र्यर्धमानं भवेत् । द्विगुणीकरणेन दिनरात्रिमाने भवनः सिद्धान्तशिरोमणौ चरघटीसहिता रहिता इत्यादिना, भास्करेणाप्येवमेव कथ्यत इति ॥ ६० ॥

अब दिन मान और रात्रिमान को कहते हैं ।

हि. भा.—उत्तर गोल में पन्द्रह १५ घटी में चरार्ध घटी को जोड़ने से और घटाने से दिनार्ध घटी और रात्र्यर्ध घटी होती है, द्विगुणित करने से दिनमान और रात्रिमान होता है । दक्षिण गोल में पन्द्रह १५ घटी में से चरार्ध घटी को घटाते से और जोड़ने से दिनार्ध और रात्र्यर्ध मान होता है, द्विगुणित करने से दिन मान और रात्रिमान होता है. इति ॥६०॥

उपपत्ति

उन्मण्डल और याम्योत्तर वृत्त के अन्तर में पन्द्रह घटी है, और स्वक्षितिज तथा उन्मण्डल के मध्य में चर घटी है, उत्तरगोल में स्वक्षितिज से उन्मण्डल ऊपर है इसलिये पन्द्रह घटी में चरघटी को जोड़ने से दिनार्धमान होता है, दक्षिण गोल में स्वक्षितिज से उन्मण्डल नीचा है इसलिये पन्द्रह घटी में से चरघटी को घटाने से दिनार्ध मान होता है, दोनों गोलों के दिनार्धमान को तीस में से घटाने से दोनों गोलों (उत्तर गोल और दक्षिण गोल) का रात्र्यर्ध मान होता है, द्विगुणित करने से दिनमान और रात्रिमान होता है, सिद्धान्तशिरोमणि में “चरघटी सहिता रहिता इत्यादि से” भास्कराचार्य भी इसी तरह कहते हैं इति ॥६०

इदानीं ग्रहाणां नक्षत्रानयनमाह

भान्यश्विन्यादीनि ग्रहलिप्ताः खल्वसूद्धृता लब्धम् ।

भुक्तिहृते गतगम्ये दिवसाः षष्ट्या गुरो घटिकाः ॥ ६१ ॥

वा. भा.—इदानीं नक्षत्रानयनार्थं सर्वग्रहाणामार्यामाह । इष्टस्फुटग्रहलिप्ताः खल्वसुभिर्विभजेत् फलभुक्तानि नक्षत्राण्यश्विन्यादीनि भवन्ति, शेषलिप्तागतसंज्ञाः ताश्च खल्वसुभ्यो विशोध्य गम्यसंज्ञा भवन्ति । ततो गत गम्ये द्वे अपि तस्यैव ग्रहस्य भुक्त्या विभजेत् । फलं दिवसाः : शेषात् षष्टिगुणात् घटिका विघटिकाश्च एवं गतात् प्राक् कालं गम्यादिष्टाभिर्हृतः चन्द्रभागेन व्यवहारेण स्फुटचन्द्रादुक्त-वन्नक्षत्रार्थतावानीय चरदलं विनाप्रमाणादिभिर्व्यवहारः इष्टावधे कार्येति प्रसिद्धत्वान्नोदाहृत इति अत्र वासना स्फुट ग्रहे मेषादिराशिगणना मेषादय-
श्विन्यादिभिर्नक्षत्राणां नक्षत्रपादैर्नक्षत्रपादाश्चाष्टादश - शत - लिप्ता-प्रमाणस्य

राशेर्नवमांशः तैश्चतुर्भिर्घट्टैः गतानि भवन्ति । चक्रलिप्पानां चन्द्रलिप्पानां मण्ड-
विंशतितमोऽंश इत्यर्थः ।

तस्माद् ग्रहलिप्पाभिरेको दिवसो भवति । तच्छेषलिप्पाभिः कियन्तो दिवसा
इति दिवसादिकालो गताह्लाद्वा कार्यः । क्षयवृद्धौ च नक्षत्रभोगस्य प्रतिमंडलव-
शाद्भूमेरुत्यासन्नोऽग्निद्वरे वा ग्रहो भवति । तस्मादुपपन्नं कक्षामंडलादिषु पूर्व-
विन्यस्तेषु सर्वं प्रदर्शयेदिति ।

वि. भा.—ग्रहलिप्पाः (ग्रहकलाः) सप्तसूदधृता (८०० एभिर्भक्ताः) सदा
लब्धं अश्विन्यादीनि भानि (नक्षत्राणि) भवन्ति, गतगम्ये (गतगम्यकले) भुक्ति
हनि (ग्रहगतिकलाभक्ते) तदा गतगम्या दिवसा भवन्ति, तच्छेषे षष्ट्या गुरो
भुक्तिहने घटिका भवन्तीति ॥ ६१ ॥

अत्रोपपत्तिः

यदि चक्रकलानुत्यग्रहगतौ सप्तविंशतिर्नक्षत्राणि लभ्यन्ते तदेषु ग्रहगतिकलायां
किमिति समागच्छन्ति गतनक्षत्राणि तत्स्वरूपम् = $\frac{२७ \times \text{ग्रहक}}{२१६००} = \frac{\text{ग्रहकला}}{८००} = \text{गत-}$
 $\text{नक्षत्र} + \frac{\text{शेष}}{८००}$ अत्र शेषं वर्तमान नक्षत्रस्य गतावयवमानम् हराच्छुद्धं तदा तद्भो-
ग्यावयवः स्यात् । ततोऽनुपातो यदि गतिकलाभिरेकं दिनं लभ्यते तदा गतकलाभि-
र्गम्यकलाभिश्च किं समागच्छन्ति गतदिनानि गम्यदिनानि च । शेषे षष्ट्या गुरो
गतिहते तदा घटिका भवन्तीति ॥ ६१ ॥

अब ग्रहों के नक्षत्रानयन को कहते हैं ।

हि. भा.—ग्रह कला को आठ सौ ८०० से भाग देने से लब्ध अश्विनी आदि नक्षत्र
होते हैं । गतकला और गम्य कला को ग्रहगति कला से भाग देने से गतदिन और गम्य दिन
होते हैं, शेष को साठ से गुणा कर गति से भाग देने से घटी होती है, इति ॥ ६१ ॥

उपपत्ति ।

यदि चक्रकलानुत्यग्रहगति में सत्ताइस २७ नक्षत्र पाते हैं तो इष्टग्रहगति कला से
क्या इससे गत नक्षत्र आते हैं $\frac{२७ \times \text{ग्रहकला}}{२१६००} = \frac{\text{ग्रहकला}}{८००} = \text{गतनक्षत्र} + \frac{\text{शेष}}{८००}$ यहां शेष
वर्तमान नक्षत्र के गतावयव है, और उसको हर में से घटाने से उसका बोनावयव होता है,
तब अनुपात करते हैं, यदि गतिकला में एक दिन पाते हैं तो उसको गतकला और गम्यकला में

क्या हमसे रत दिन और गम्य दिन आते हैं। शेष को साठ से गुणा कर गति से भाग देने से घटी होती है। सिद्धान्त शिरोमणि में 'ग्रहकलाः सरवीन्दुकला हृताः' इत्यादि से भाङ्करा चार्थ भी इसी वान को कहते हैं. ॥ ६१ ॥

इदानीं तिथ्यानयनमाह

अर्कोनचन्द्रलिप्ताः खयमस्वर ७२० भाजिताः फलं तिथयः ।

गतगम्ये षष्टिगुणे भुक्तयन्तरभाजिते घटिकाः ॥ ६२ ॥

वा. भा.—इदानीं तिथ्यानयनार्थमार्यामाह स्पष्टार्थेयमार्या अमावास्यान्ते चन्द्र-सूर्यौ तुल्यावेकसूत्रगौ भवतस्तत्र प्रतिदिनं पश्चादवलम्बते । तस्माद्विमुक्तिं विगोध्य गत्योरन्तरं सिद्धं भवति यस्मादमावास्यान्तात् द्वावपि प्रवृत्तौ तयोश्चान्तरे द्वादशभिर्भागैरेका तिथिर्भवति । यतश्च चक्रांशकानां त्रिंशद्भागेन द्वादशभागा भवन्ति । तयोश्चान्तरे चक्रममावास्यान्ते भवति द्वादशभिश्च भागैः खयमस्वरसंख्या लिप्ता भवति । अतोऽर्कोनचन्द्रलिप्ता खयमस्वरभाजिताफलं तिथीत्युक्तम् जेपेण सह त्रैराशिकं यदि भुक्तान्तरेण षष्टिघटिका लभ्यन्ते तच्छेषाभिलिप्ताभिः कियत् इति शेषं प्राग्वत् । अथ सूर्यो गोलाध्यायेपि त्रिदिवसप्रतिपादने विस्तरेण मया व्याख्यात एवेति । रवि चन्द्रान्तरदर्शनार्थमाह ॥

वि. भा.—अर्कोनचन्द्रलिप्ताः (रविचन्द्रान्तरकलाः) खयमस्वरभाजिताः (७२० एभिर्भक्ताः) फलं गततिथयो भवन्ति, गता हराच्छुद्धास्तदा गम्या भवन्ति, गतगम्यकले षष्ठ्या गुणिते भुक्तयन्तरभाजिते (रविचन्द्रगत्यन्तरकलाभिर्भक्ते) तदा गतघटिका गम्यघटिकाश्च भवन्तीति ॥ ६२ ॥

अत्रोपपत्तिः

अमान्ते रविचन्द्रावेकत्रैव भवतः (दर्शः सूर्येन्दुसङ्गम इत्युक्तेः) ततोऽनन्तरं चन्द्रोऽधिकगतित्वादग्रतो गच्छति, एवं गच्छन् चन्द्रः पुनरविणा सह यदा मिलति तदा द्वितीयोऽमान्तश्चान्द्रमासपूर्तिश्च भवति तत्र च रविचन्द्रयोरगत्यन्तरांशः ३६०, ततोऽनुपातो यदि रविचन्द्रगत्यन्तरांशेन ३६० तत्तुल्येन त्रिंशत्तिथयो (चान्द्रमासस्य त्रिंशत्तिथ्यात्मकत्वात्) लभ्यन्ते तदेष्टरविचन्द्रगत्यन्तरेण किमिति

$$\begin{aligned} \text{फलं गतास्तिथयस्तत्स्वरूपम्} &= \frac{३० \times \text{रविचन्द्रान्तरांश}}{३६०} = \frac{३० \times \text{रविचन्द्रान्तरांश} \times २}{३६० \times २} \\ &= \frac{६० \times \text{रविचन्द्रान्तरांश}}{७२०} = \frac{\text{रविचन्द्रान्तरकला}}{७२०} = \text{गतति} + \frac{\text{शेष}}{७२०} \text{ अत्र शेषं} \end{aligned}$$

वर्त्तमानतिथेर्यन्तावयरूपम् । तत् हराच्छुद्धं तदा वर्त्तमानतिथेर्भोग्यावयवो

भवति । ततोऽनुपातो यदि गत्यन्तरकलाभिः षष्टिघटिका लभ्यन्ते तदा गतकलाभिर्गम्यकलाभिश्च किं समागच्छन्ति गतघटिका गम्यघटिकाश्चेत्यनेनाचार्योक्तमुपपद्यते,

$$\text{अथ पूर्वोक्तगततिथिस्वरूपम्} = \frac{३० \times \text{रविचन्द्रान्तरांश}}{३६०} = \frac{\text{रविचन्द्रान्तरांश}}{१२} = \text{गतति}$$

+ $\frac{\text{शे}}{१२}$, अत्र शेषं वर्त्तमानतिथेर्येगतावयवरूपम् तद्वराच्छुद्धं भोग्यं स्यात् । ततोऽनु-

$$\text{पातः पूर्ववत्} = \frac{६० \times \text{गतकला}}{\text{गत्यन्तरकला}} = \frac{\text{गतविकला}}{\text{गत्यन्तरक}} = \text{गतघटिकाः । } \frac{६० \times \text{भोग्यकला}}{\text{गत्यन्तरक}} =$$

$\frac{\text{भोग्यविकला}}{\text{गत्यन्तरक}}$ भोग्यघटिकाः एतेन “मिहिर विरहितेन्दोरंशकेभ्यो द्विचन्द्रैः १२ गत-

तिथिनिचयः स्यात्तत्र शेषं गताख्यम् । तदपि हरविशुद्धं गम्यकं तद्विलिप्ता गतिवि-
वरविभक्ता यातयेयाख्यनाड्यः” श्रीपत्युक्तमुपपद्यते, सिद्धान्तशिरोमणौ भास्करे-
णापी ‘रविरसैर्विरवीन्दुलवाहता इत्यादिना’ दमेव कथ्यत इति ॥ ६२ ॥

अब तिथ्यानयन को कहते हैं ।

हि. भा.—रवि और चन्द्र की अन्तरकला को सात सौ बीस ७२० से भाग देने से लब्धि गत तिथि होती है, गत को हर में से घटाने से गम्य होता है, गत कला और गम्य कला को साठ ६० से गुणा कर गत्यन्तर से भाग देने से गत घटी और गम्य घटी होती है इति. ॥ ६२ ॥

उपपत्ति

अमान्त काल में रवि और चन्द्र एक ही स्थान में रहते हैं, उसके बाद चन्द्र शीघ्रगति होने के कारण रवि से आगे चला जाता है इसतरह प्रतिदिन चलते चलते फिर रवि के साथ मिलता है तब द्वितीय अमान्त होता है, और चन्द्र मास की पूर्ति होती है, तथा वहाँ रवि और चन्द्र के गत्यन्तरांश = ३६०° होता है, तब अनुपात करते हैं यदि रवि और चन्द्र के तीन सौ साठ ३६० अंश तुल्य गत्यन्तरांश में तीस ३० तिथि (१ चन्द्रमास तीस तिथि के होते हैं) पाते हैं तो इष्ट रवि चन्द्र के गत्यन्तरांश में क्या इससे गततिथि प्रमाण आता है ।

$$\frac{३० \times \text{रविचन्द्रान्तरांश}}{३६०} = \frac{३० \times \text{रविचन्द्रान्तरांश} \times २}{३६० \times २} = \frac{६० \times \text{रविचन्द्रान्तरांश}}{७२०} =$$

$$\frac{\text{रविचन्द्रान्तर कला}}{७२०} = \text{गतनक्षत्र} + \frac{\text{शे}}{७२०} \text{ यहाँ शेष वर्त्तमान तिथि का गतावयव रूप है}$$

उसको हर में से घटाने से वर्त्तमान तिथि का भोग्य अवयव होता है, तब अनुपात करते हैं । यदि गत्यन्तर कला में साठ घटी पाते हैं तो गत कला और गम्य कला के बीच इससे गत घटी

और गम्य घटी आती है इससे आचार्योक्त उपपन्न हुआ । पूर्वोक्त गततिथि स्वरूप=

$$\frac{३० \times \text{रविचन्द्रान्तरांश}}{३६०} = \frac{\text{रविचन्द्रान्तरांश}}{१२} = \text{गतति} + \frac{\text{शेष}}{१२}$$
 यहां भी शेष वर्तमान तिथि

का गतावयव रूप है । उसको हर १२ में से घटाने से भोग्य होता है । तब अनुपात करते हैं

$$\frac{६० \times \text{गनकला}}{\text{गत्यन्तरक}} = \frac{\text{गत विकला}}{\text{गत्यन्तरक}} = \text{गतघटी}, \frac{६० \times \text{भोग्यकला}}{\text{गत्यन्तरक}} = \frac{\text{भोग्य विकला}}{\text{गत्यन्तरक}} = \text{भोग्यघटी}$$

इससे 'मिहिरविरहिनेन्दो रंगकेम्बो द्विचन्द्रः' इत्यादि संस्कृतोपपत्ति में लिखित श्रीपति का पद्य उपपन्न होना है । मिद्धान्ति शिरोमणि में भास्कराचार्य भी 'रविरसैविरवीन्दुलवाहता' इत्यादि से इसी को कहते हैं ॥ ६२ ॥

इदानीं योगानयनमाह

रविचन्द्रयोगलिप्ताः खल्वसुभिर्भाजिताः फलं योगाः ।

गतगम्ये षष्टिगुणे भुक्तिसमासोद्धृते नाड्यः ॥ ६३ ॥

सु. भा.—स्पष्टार्थम् । संप्रत्युपलब्धचतुर्वेदाचार्यटीकायामियमार्या नोपलभ्यते ॥ ६३ ॥

वि. भा.—रविचन्द्रयोगकलाः ८०० एभिर्भक्तास्तदा लब्धं गतयोगा भवन्ति, गतगम्यकले षष्ट्यागुणिते भुक्तिसमासोद्धृते (रविचन्द्रगतियोगभक्ते) तदा गता नाड्यो गम्यनाड्यश्च भवन्तीति ॥ ६३ ॥

अत्रोपपत्तिः

रविचन्द्रयोगगतियोगेन योगा जायन्ते, यदा रविचन्द्रयोगगतियोगः=२१६०० तदा सप्तविंशतियोगाभवन्त्यतोऽनुपातो यदि रविचन्द्रयोगगतियोगकलाया २१६०० भेत्तु त्यायां सप्तविंशतियोगा लभ्यन्ते तदेष्टगतियोगे किं समागच्छन्ति गतयोगा-स्तत्स्वरूपम् = $\frac{२७ \times \text{गतियोग}}{२१६००} = \frac{\text{गतियोग}}{८००} = \text{गतयोग} + \frac{\text{शेष}}{८००}$, अत्रापि शेषं वर्त्तमानयोगस्य गतावयवरूपम् । एतत् हराच्छुद्धं तदा वर्त्तमानयोगस्य भोग्यावयवरूपम् । ततोऽनुपातो यदि गतियोगकलायां षष्टिघटिका लभ्यन्ते तदा गतकलायां गम्यकलायां च किं समागच्छन्ति गतनाडिका गम्यनाडिकाश्चेति । सिद्धान्तशेखरे श्रीपतिना “रविविषुयुतिलिप्ताः खान्नागौ ८०० विभक्ताः फलमिह गतयोगान् विद्धि विष्कम्भपूर्वात् । तदनु च गतगम्याः सत्त्वं ६० निघ्ना विभक्ताः स्वगतियुतिकलाभिर्नाडिका भुक्तभोग्याः” जेनाऽऽचार्योक्तानुरूपमेव सर्वं कथितमिति ॥ ६३ ॥

अब योगानयन को कहते हैं ।

हि. भा.—रवि और चन्द्र की योगकला (गतियोग कला) को आठ सौ ८०० से भाग देने से लब्ध गत योग होते हैं । गतकला और गम्यकला को साठ से गुणा कर गति योग द्वारा भाग देने से गतनाड़ी और गम्य नाड़ी होती है इति ॥ ६२ ॥

उपपत्ति ।

रवि और चन्द्र के गति योग से योग बनते हैं, जब रवि और चन्द्र के गतियोग = २१६०० तब सत्ताईस २७ योग होते हैं, इससे अनुपात करते हैं, यदि रवि और चन्द्र के गति योग कला २१६०० एतत्तुल्य में सताइस योग पाते हैं तो इष्ट गति योगकला में क्या इससे गतयोग प्रमाण आता है, $\frac{२७ \times \text{गतियोगक}}{२१६००} = \frac{\text{गतियोगक}}{८००} = \text{गतयो} + \frac{\text{शे}}{८००}$ यहां शेष वर्तमान योग के गतावयव रूप है । उसको हर ८०० में से घटाने से वर्तमान योग का भोग्यावयव रूप होता है, तब अनुपात करते हैं यदि गतियोग कला में साठ ६० घटी पाते हैं तो गतयोगकला में और गम्य योग कला में क्या इससे गत नाड़ी और गम्य नाड़ी आती है । सिद्धान्तशेखर में श्रीपति ने 'रविविद्युतिलिप्ता इत्यादि संस्कृतोपपत्ति में श्लोक से आचार्यों-क्तानुरूप ही सब कुछ कहा है ॥ ६३ ॥

इदानीं रविचन्द्रांतरमाह

राश्यंशकलाविकलाः स्फुटमासान्तेश्लिलिप्तिका विकलाः ।

पक्षान्ते तिथ्यन्ते समा रवीन्द्रोः कलाविकलाः ॥ ६४ ॥

वा. भा.—अमावास्यान्ते स्फुटार्कचंद्रयोः किमप्यन्तरं भवति । तस्मात्ते-
राश्यादयः समा एवोपयुं परिस्थितत्वाद्भूमध्यस्थितस्य द्रष्टुः पक्षान्ते चार्धवक्रां-
तरितौ द्वावपि भवतोऽस्तत्र भागादयश्च समा एव राश्यश्चभिन्नाः प्रतिदिनमभे-
दादिति ।

वि. भा.—स्फुटमासान्ते रवीन्द्रोः (रविचन्द्रयोः) राश्यंशकलाविकलाः समा-
भवन्त्यर्थाद्राश्याद्यवयवाः समा भवन्ति, पक्षान्ते रविचन्द्रयोरंशलिप्तिका विकलाः
समा भवन्त्यर्थाद्रविचन्द्रावंशाद्यवयवेन तुल्यौ भवतः । तिथ्यन्ते रवीन्द्रोः कला
विकलाः समा भवन्तीति ॥ ६४ ॥

अत्रोपपत्तिः

रविचन्द्रयोरन्तरांशा यदा द्वादशांशसमास्तदैका तिथिर्भवति, स्फुटमासान्ते

त्रिगन्तिथयोऽनस्तत्र रविचन्द्रान्तरांशः = $३० \times १२ = ३६०^\circ$ वा शून्यसमा अतो रवि-
चन्द्रौ राश्याद्यवयवैस्तत्र समौ भवतः पक्षान्ते पञ्चदश तिथयोऽनस्तत्र रविचन्द्रान्त-
रांशः = $१५ \times १२ = १८०^\circ = ६$ राशयः । अतस्तत्र रविचन्द्रावशाद्यवयवैः समौ
भवतः कथमन्यथा तयोरन्तरे केवलं राशय एव तिष्ठन्ति, कस्मिन्नपि तिथ्यन्ते रवि-
चन्द्रयोरन्तरांश द्वादशभक्ता एव भवितुमर्हन्ति, तेन तिथ्यन्ते कलाविकलासमत्वा-
देव केवलमंशा उत्पद्यन्ते, सिद्धान्तशेखरे श्रीपतिना 'मासान्ते समताऽर्कशीतमहसोः
क्षेत्रेण राश्यादिना पक्षान्ते पुनरेतयोः सदृशता भागादिना जायते, अन्यस्याश्च तिथे-
र्विरामसमये लिप्तादिना तुल्यता, ज्ञेनाऽऽचार्योक्तानुरूपमेव कथ्यते । लल्लाचार्येणा
'मासान्ते रविशशिनौ समौ भवेतां पक्षान्ते लवकलिकाविलिप्तिकाभिः । अन्यस्या
अपि च तिथेः सदाऽवसाने तुल्यौ स्तः खलु कलिकाविलिप्तिकाभिः' पीदमेव कथ्यत
इति ॥ ६४ ॥

अब रवि और चन्द्र के अन्तर को कहते हैं ।

हि. भा.—स्फुटमासान्त में रवि और चन्द्र के राशि, अंश, कला, और विकला सम
होती है अर्थात् राशाद्यवयव से दोनों बराबर होते हैं । तिथ्यन्त में उन दोनों के कला,
विकला बराबर होती है अर्थात् कलाद्यवयव से बराबर होते हैं इति ॥ ६४ ॥

उपपत्ति ।

रवि और चन्द्र के अन्तरांश जब बारह अंश होते हैं तब एक तिथि होती है, स्फुट-
मासान्त में तीस तिथियां होती हैं इसलिये वहाँ रवि चन्द्रान्तरांश = $३० \times १२ = ३६०$ वां
शून्य के बराबर, अतः वहाँ रवि और चन्द्र राश्याद्यवयवों से बराबर होते हैं । पक्षान्त में
पन्द्रह १५ तिथियां होती हैं इसलिये रवि चन्द्रान्तरांश = $१५ \times १२ = १८० = ६$ राशि, अतः
वहाँ रवि और चन्द्र अंशाद्यवयवों से बराबर होती है, क्योंकि उन दोनों के अन्तर करने से
केवल राशि ही रहती है । किसी भी तिथ्यन्त में रवि चन्द्र का अन्तरांश बाहर से विभक्त ही
रहता है इसलिये तिथ्यन्त में रवि और चन्द्र कलाद्यवयव से बराबर होते हैं । सिद्धान्त शेखर
में श्रीपति 'मासान्ते समताऽर्कशीत महसो, इत्यादि । संस्कृतोपपत्ति में लिखित श्लोक से
आचार्योक्तानुरूप ही कहते हैं, लल्लाचार्य भी 'मासान्ते रवि शशिनौ समौ भवेताम्' इत्यादि,
संस्कृतोपपत्ति में लिखित श्लोक से इसी बात को कहते हैं इति ॥ ६४ ॥

इदानीं स्थिरकरणान्याह

कृष्णचतुर्विंशन्ते शक्रुनिः पर्वणि चतुष्पदं प्रथमे ।

तिथ्यर्थेऽन्ते नागं किस्तुष्णं प्रतिपदाद्यर्थे ॥ ६५ ॥

भक्ता लब्धमेकेन हीनं, अगहृतशेषे (सप्तभक्तावशिष्ट) बवादीनि चर करणानि
भवन्ति अन्यत्कर्मतिथिसाधनवत्कार्यमिति ॥ ६६ ॥

अत्रोपपत्तिः

तिथिसाधनार्थं यदि ३६०° तुल्य रविचन्द्रयोग्यत्यन्तरेण त्रिंशत्तिथयो लभ्यन्ते
तदेष्टरविचन्द्रान्तरांशे किमिति जाता गतास्तिथयः = $\frac{३० \times \text{रविचन्द्रान्तरांश}}{३६०} =$
 $\frac{\text{रविचन्द्रान्तरांश}}{१२}$ ततस्तिथिद्विगुणाकरणानीत्यतः करणानि = $\frac{२ \times \text{रविचन्द्रान्तरांश}}{१२}$
= $\frac{\text{रविचन्द्रान्तरांश}}{६} = \frac{\text{रविचन्द्रान्तरांश} \times ६०}{६ \times ६०} = \frac{\text{रविचन्द्रान्तरकला}}{३६०}$, चत्वारि
स्थिरकरणानि येषां स्थितिः पूर्वश्लोकेन स्पष्टाऽस्ति, किंस्तु घ्न संज्ञक स्थिर
करणस्य प्रतिपदार्धगतत्वात् बवादीनां च शुक्लप्रतिपदोऽन्त्यार्धमारभ्य प्रवृत्तेः,
पूर्वं $\frac{\text{रविचन्द्रान्तरक}}{३६०}$ लब्धेषु चैकमूनीक्रियत, ततः सप्तभक्तेऽवशेषं बवादिकरणं
भवेत् । अत्रापि षट्त्रिंशत्तिथ्याद् गतगम्याद् गत्यन्तरेण भक्ताद् वर्तमानकरणस्य
गतगम्यघटयो भवन्ति, सिद्धान्तशेखरे “भानुहीनशशिभागसमूहात् स्याद्ववादिकरणं
रसभक्तात् । रूपहीनमगभाजितशेषं शेषक्रमं तिथिवच्च विधेयम्” इत्यनेन श्रीपतिना
रविरसैर्विरीन्दुलवाहृता इत्यादिना भास्करेण च रविचन्द्रान्तरांशवशेन करणा-
नयनं कृतम् । आचार्येण (ब्रह्मगुप्तेन) रविचन्द्रान्तर कलावशेन तज्ज्ञानं क्रियत
इति ॥ ६६ ॥

अब चर करणों को कहते हैं ।

हि. भा. — रवि और चन्द्र की अन्तर कला को तीन सौ साठ ३६० से भाग देने से जो लब्ध हो उसमें से एक घटा कर सात से भाग देने से शेष ववादि करण होते हैं, अन्य कर्म (गत घटी, गम्य घटी साधन) तिथिसाधनवत् करना चाहिये इति ॥ ६६ ॥

उपपत्ति ।

तिथि साधन के लिये यदि तीन सौ साठ ३६० रवि और चन्द्र के गत्यन्तरांश में तीस तिथि पाते हैं तो इष्ट रवि चन्द्रान्तरांश में क्या इससे गततिथि आती है, $\frac{३० \times \text{रविचन्द्रान्तरांश}}{३६०} = \frac{\text{रविचन्द्रान्तरांश}}{१२} =$ गततिथि, तिथि को द्विगुणित करने से करण

होते हैं इस नियम से $\frac{२ \times \text{रविचन्द्रान्तरांश}}{१२} = \frac{\text{रविचन्द्रान्तरांश}}{६} = \frac{\text{रविचन्द्रान्तरांश} \times ६०}{६ \times ६०}$
 $= \frac{\text{रवि चन्द्रान्तरकला}}{३६०} =$ करण, चार स्थिर करण है जिनकी स्थिति पूर्वश्लोक में कही गयी

है, शुक्ल पक्ष की प्रति पदा के पूर्वार्ध में किंस्तुघ्न करण के रहने के कारण तथा शुक्लपक्ष की प्रतिपदा के परार्ध से ववादि करणों की प्रवृत्ति के कारण पूर्व $\frac{\text{रविचन्द्रान्तर कला}}{३६०}$ लब्धि में से एक घटाना चाहिये, तब सात से भाग देकर जो शेष रहता है वह ववादि करण होता है । यहां भी गतकला और गम्यकला को साठ से गुणा कर गत्यन्तर से भाग देनेसे वर्तमान करण की गतघटी और गम्य घटी होती है, सिद्धान्तशेखर में “भानु हीनशशिभागसमूहात्” इत्यादि संस्कृतोपपत्ति में लिखित श्लोक से ‘श्रीपति, तथा ‘रविरसैर्विरवीन्दुलवा हृता’ इत्यादि से भास्कराचार्य ने रविचन्द्रान्तरांश से करणानयन किया है । आचार्य ने रविचन्द्रान्तर कला बश से उन का साधन किया है, कोई विशेषता नहीं है इति ॥ ६६ ॥

इदानीमवशिष्टं स्फुटगत्युत्तराध्याये वक्ष्यामीत्येतदर्थमाह ।

इह नोक्तानि बहुत्वात् स्पष्टगतेरुत्तरेऽभिधास्यामि ।

अब त्रिप्रश्नाधिकार प्रारम्भ किया जाता है

तीन प्रश्नों (दिशा, देश, काल) का उत्तर जिसमें कहा जाता है, वह त्रिप्रश्नाधिकार है, उसमें पहले दिशा ज्ञान को कहते हैं ।

हि. भा.—पूर्वकपाल में पश्चिमकपाल में तुल्यछायाप्रद्वय में जो दो बिन्दु हैं उनमें प्रथम बिन्दु पश्चिम दिशा है, द्वितीय बिन्दु पूर्व दिशा है, पूर्वकपाल और पश्चिम-
कपाल में तुल्यछायाप्रद्वय की जो कान्ति होती है उसके वश से भेद होता है, दोनों छायाप्रद्वय के मध्य से शङ्कुमूलपर्यन्त जो रेखा होती है वह दक्षिणोत्तर रेखा है, उसी में दक्षिण दिशा और उत्तर दिशा होती है । जलादि से समान की हुई पृथ्वी में इष्ट दिन में मध्याह्न-
कालिक छाया व्यासार्ध से वृत्त बनाकर उसके केन्द्र में द्वादशा १२ इयुल शङ्कु स्थापित करना, सूर्य के पूर्वकपाल में रहने से उस शङ्कु का छायाप्र उस वृत्तपरिधि में जहाँ प्रवेश करता है वह बिन्दु स्थूल पश्चिम दिशा है, पश्चिम कपाल में सूर्य के रहने से शङ्कु का छायाप्र पूर्वभाग में उस वृत्त परिधि में निर्गत होता है वह स्थूल पूर्व दिशा है, दोनों बिन्दु (स्थूल पूर्व-
पश्चिम) गतरेखा स्थूल पूर्वापर रेखा होती है, उसमें दोनों छायाओं के मध्य से शङ्कु मूलगत रेखा दक्षिणोत्तर रेखा होती है इति ॥१॥

उपपत्ति

छायाप्रवेशकालिक और निर्यसकालिक कान्ति की अनुत्पत्ता से दोनों कालिक अथवा नौ अनुत्पत्त होती हैं कान्ति = छायाप्रवेशकालिक कान्ति । कान्ति = छायाप्रनिर्गमकालिक

क्रान्ति, $\frac{\text{त्रि.ज्याक्रां}}{\text{ज्याल}} = \text{अग्रा}$, $\frac{\text{त्रि.ज्याक्रां}}{\text{ज्याल}} = \text{अग्रा}$ दोनों का अन्तर करने से $\frac{\text{त्रि.ज्याक्रां}}{\text{ज्याल}}$

$\frac{\text{त्रि.ज्याक्रां}}{\text{ज्याल}} = \frac{\text{त्रि.}}{\text{ज्याल}} (\text{ज्याक्रां} - \text{ज्याक्रां}) = \text{अग्रा} - \text{अग्रा} = \text{अग्रान्तर} = \text{भुजान्तर}$, इसको छायाकर्ण गोल में लाते हैं। अनुपात करते हैं यदि त्रिज्याव्यासार्ध में यह अग्रान्तर पाते हैं तो छायाकर्ण व्यासार्ध में क्या इससे छायाकर्ण व्यासार्ध में अग्रान्तर आया $\frac{\text{त्रि.छाक.}}{\text{ज्याल.त्रि}}$

$(\text{ज्याक्रां} - \text{ज्याक्रां}) = \frac{\text{छाक.}}{\text{ज्याल}} (\text{ज्याक्रां} - \text{ज्याक्रां}) = \text{छायाकर्णगोल में अग्रान्तर}$ इससे पूर्व-

बिन्दु के चालनवश से वास्तव पूर्वापर रेखा की समानान्तर रेखा का ज्ञान होता है, केन्द्र-बिन्दु से उसकी समानान्तर रेखा वास्तव पूर्वापर रेखा होती है, पूर्वापर रेखा की समानान्तर रेखा के अर्ध बिन्दु से उसके ऊपर लम्बरेखा या पूर्वापर रेखा के अर्ध बिन्दु (केन्द्रबिन्दु) से उसके ऊपर लम्बरेखा दक्षिणोत्तर रेखा होती है, सिद्धान्तशेखर में “छायानिर्गमनप्रवेशतमयार्कक्रान्तिजीवान्तरं” इत्यादि संस्कृतोपपत्ति में लिखित श्लोक श्रीपतिप्रकार को देव कर भास्कराचार्य ने “तत्कालापमवीथयोस्तु विवरात् इत्यादि” सिद्धान्तशिरोमणि में कहा है। लेकिन छायाकर्ण वृत्तशरिणि में अग्रान्तर या भुजान्तर दान देना अनुचित है इसलिए श्रीपत्यादि कथित प्रकार से स्फुट पूर्वापर दिशा का ज्ञान टीक से नहीं हो सकता है, अतः वास्तव ज्ञान के लिए युक्ति बतलाते हैं।

यहाँ संस्कृतोपपत्ति में लिखित (क) क्षेत्र को देखिये। पू = स्थूल पूर्वदिशा, प = स्थूल पश्चिम दिशा, पूप रेखा वास्तवपूर्वापर रेखा की असमानान्तर रेखा, पू बिन्दु से अग्रान्तर तुल्य या भुजान्तर तुल्य पूर्वाज्या रूप रेखा (पून) दिये (रे. ४ अध्याय युक्ति से) पन रेखा कीजिए, $< \text{पूनप} = ९०$, तब यहीं पन रेखा वास्तव पूर्वापर रेखा की समानान्तर होती है, केन्द्र बिन्दु से इसकी समानान्तर रेखा वास्तव पूर्वापर रेखा होगी, इस तरह वास्तविक पूर्व पश्चिम दिशाओं का ज्ञान हुआ, केन्द्र बिन्दु से पूर्वापर रेखा के ऊपर लम्ब रेखा दक्षिणोत्तर रेखा होती है. इस तरह दक्षिणोत्तर दिशाओं का भी ज्ञान हुआ इति ॥१॥

अब भाभ्रमरेखा वश से दिग्ज्ञान को कहते हैं

हि. भ७.—इष्ट दिन में जलादि से समान की हुई पृथ्वी पर मध्यच्छाया व्यासार्ध से निश्चित वृत्त के केन्द्र में स्थित शङ्कु की तीन काल की छाया जानकर उन तीनों के अग्र बिन्दुओं से इष्ट कर्कट से तीन वृत्त बनाकर उनके योग से दो मत्स्य (मछली के आकार) बनाकर उनके मुख और पुच्छ के मध्यगत रेखाद्वय का योग जहाँ होता है उसके उत्तर गोल में दक्षिण दिशा समझनी चाहिये, यदि जिनाल्पाक्षांश देश (चीबीश भंश से कम अक्षांश वाला देश) में कभी शङ्कु मूल से दक्षिण छायात्र में वह योग हो तब वह उत्तर दिशा समझनी

चाहिये, मत्स्यद्वय के मूल और पुच्छगत मूत्रों के योग में जो वृत्त परिधि होती है, वह छाया-
स्पर्शकारक वृत्त (छायाभ्रमणवृत्त) होता है, इसलिये वह वृत्तरेखा ही छायाभ्रमण रेखा
होती है, शङ्कु मूल और छायाभ्रमण वृत्त का जो अन्तर है, वही मध्यच्छाया होती है,
वह उत्तर या दक्षिण होती है, त्रिनाशिकाशांश देश (बीबीअ अंग से अधिक भ्रंशंग
वाला देश) में मध्यच्छाया सदा उत्तर होती है, उत्तरगोल में त्रिनाशिकाशांश देश में जब
रवि की उत्तरा क्रांति भ्रंशंगाधिक होती है तब मध्याह्नकाल में शङ्कु की छाया
दक्षिणाभिमुखी होती है, सूर्यसिद्धान्त में भी 'इष्टेऽह्नि मध्ये प्राक् पदवान् इत्यादि से'
इसी तरह कहा गया है, सत्त्वाचार्य 'यो मत्स्यपुच्छमुखनिर्गतरज्जुयोगः' इत्यादि संस्कृत-
भाष्य में लिखित श्लोक से तथा 'मत्स्योदरद्वयममूत्रयुतेष्व तस्याः' इत्यादि से तथा
'शङ्कुप्रभाभ्रमणमण्डलयोः' इत्यादि से भी, श्रोपति भी प्राचार्योक्तानुरूप ही कहते हैं
इति ॥ २-३ ॥

उपपत्ति

यदि एक दिन में रवि की क्रांति स्थिर हो तब ग्रहोरात्र वृत्त के प्रतिबिन्दुस्थ
रवि केन्द्रों से शङ्कवर्षगत किरणमूत्र (शङ्कवर्षगत रेखायें) जहाँ-जहाँ पृष्ठक्षितिज बरातल में
लगते हैं उन स्थानों से शङ्कु मूल तक छाया है, छायाओं के स्वरूप देखने से सिद्ध होता है
कि शङ्कु के भ्रम से ग्रहोरात्रवृत्त के आकार पर सूची बनाइये उसको पृष्ठक्षितिज
बरातल से काटने से जैसा वक्र बनता है वैसा ही छायाभ्रमण मार्ग होता है, मेरु वासियों
का क्षितिजवृत्त नाड़ीवृत्त है, वह ग्रहोरात्रवृत्त के समानान्तर है इसलिये शङ्कवर्ष से
ग्रहोरात्रवृत्ताधारा विषमसूची पृष्ठक्षितिजबरातल (नाड़ीवृत्त बरातल के समानान्तर
बरातल) से कटित होकर कटित प्रदेश को वृत्ताकार बनाती है, इससे सिद्ध होता है कि
मेरु में सदा छायाभ्रमणमार्ग वृत्ताकार होता है, सूर्यसिद्धान्तकार, सत्त्वाचार्य,
ब्रह्मगुप्त आदि प्राचार्यों ने छायाभ्रमणमार्ग वृत्ताकार को स्वीकार किया है वह मेरु ही में
ठीक हो सकता है, क्योंकि मेरु से अल्पत्र साध देश में न्यूनान्शिक शङ्कु वर्ष से रेखा में, वृत्त
में, परबलय में, दीर्घवृत्त में अतिपरबलय में छायाभ्रमण होता है, निरक्ष देश में विषुवदिन
में नाड़ीवृत्त में रवि के भ्रमण से और नाड़ीवृत्त बरातल में शङ्कवर्ष के रहने के कारण
शङ्कवर्ष से नाड़ीवृत्त रूप ग्रहोरात्रवृत्ताधारा सूची का अभाव होता है इसलिये निरक्षक्षितिज
बरातल और नाड़ीवृत्त बरातल की ओररेखा (निरक्षोष्माधर रेखा) भाभ्रमरेखा होती है,
सब देशों में सदा छायाभ्रमण वृत्त में नहीं होता है इस विषय को देखा करके ही सिद्धान्त-
शिरोमणि में आस्कराचार्य ने 'भातितवाद् भाभ्रमलं न सद्' इत्यादि से वृत्ताकार छायाभ्रमण
मार्ग का खण्डन किया है, जो बहुत ही ठीक है इति ॥ २-३ ॥

छायाकर्णो किं समागच्छति छायाकर्णवृत्ताग्रा = $\frac{\text{अग्रा} \times \text{छायाकर्ण}}{\text{त्रि.}}$, छायाकर्ण-

गोले शङ्कुतलं पलभातुल्यं भवति कथमिति प्रदर्शयते अथ $\frac{\text{पलभा} \cdot \text{शङ्कु.}}{१२}$ शङ्कुतल,

परन्तु, $\frac{१२ \times \text{त्रि.}}{\text{छायाकर्ण}}$ शङ्कु उत्थापनेन $\frac{\text{पलभा} \cdot १२ \cdot \text{त्रि.}}{१२ \times \text{छायाकर्ण}} = \text{शङ्कु. तल, छायाकर्णव्यासार्धे}$

परिणाम्यते $\frac{\text{पलभा} \cdot १२ \cdot \text{त्रि.} \times \text{छायाकर्ण}}{१२ \times \text{छायाकर्ण} \times \text{त्रि.}} = \text{पलभा} = \text{शङ्कुतलम्} । अतश्छायाकर्ण-$

गोलेऽग्रापलभयोः संस्कारेण भुजो भवेत् । यतः अग्रा \pm शङ्कुतल = भुजः ।
भास्कराचार्येण छायाग्रे पूर्वापररेखयोरन्तरं भुज इति स्वीकृत्य छायाकर्णवृत्ताग्रा
व्यस्तगोला पलभा चोत्तरा कल्पिता, आचार्येण लघुशङ्कुमूलपूर्वापररेखयोरन्तरं
भुज इति स्वीकृत्याग्रा पलभे यथा दिक्के एव स्थापिते, भुजस्याग्रे इत्यस्याग्रे
सम्बन्ध इति ॥४॥

अब द्वादशाङ्गुल शङ्कु के भुजानवन को कहते हैं

हि. भा.—रवि की अग्रा को छाया कर्ण से गुणा कर त्रिज्या से भाव देने से छाया-
वृत्त में रवि की अग्रा होती है, पलभा सर्वदा दक्षिण दिशा की होती है, उन दोनों का अन्तर
और योग (कर्णवृत्ताग्रा और पलभा के मिला दिशा में अन्तर और एक दिशा में योग) करने
से संस्कार दिशा का भुज होता है इति ॥४॥

उपपत्ति

स्वोदयास्तसूत्र और पूर्वापरसूत्र का अन्तर अग्रा है शङ्कुमूल से पूर्वापरसूत्र के

ऊपर लम्ब शङ्कु तल है, अग्रा और शङ्कु तल का संस्कार करने से शङ्कु मूल से पूर्वापरसूत्र के ऊपर लम्ब भुज होता है, त्रिज्या व्यासार्ध में यदि त्रिज्याग्रीय अग्रा पाते हैं तो छाया-

कर्णों में क्या इससे आती है छायाकर्णवृत्ताग्रा = $\frac{\text{अग्रा} \times \text{छायाकर्ण}}{\text{त्रि}}$, परन्तु छायाकर्ण गोल में

पलभा शङ्कु तल के बराबर होती है जैसे $\frac{\text{पलभा. शङ्कु}}{१२} = \text{शङ्कु तल}$, $\therefore \frac{१२ \times \text{त्रि}}{\text{छायाकर्ण}} = \text{शङ्कु}$.

अतः उत्पापन से $\frac{\text{पलभा. } १२ \times \text{त्रि}}{१२. \text{छायाकर्ण}} = \text{शङ्कु तल}$, छायाकर्ण गोल में परिणामन करते हैं

$\frac{\text{पलभा. } १२. \text{त्रि} \times \text{छायाकर्ण}}{१२. \text{छायाकर्ण} \cdot \text{त्रि}} = \text{पलभा} = \text{शङ्कु तल}$, इसलिए छायाकर्ण गोल में अग्रा और

पलभा के संस्कार से भुज होता है, भास्कराचार्य ने छायाग्र और पूर्वापररेखा के अन्तर को भुज स्वीकार कर छायाकर्ण वृत्ताग्रा को व्यस्त गोलक और पलभा को उत्तर कल्पित किया है यहां भाचार्य लघुशङ्कु मूल और पूर्वापररेखा के अन्तर को भुज स्वीकार कर अग्रा और पलभा को यथादिकक (जिस दिशा के जो हैं उसी दिशा के) ही स्थापित किये हैं, भुजस्याग्रे इसका प्रागे से सम्बन्ध है इति ॥४॥

वि. भा.—प्राच्यपरायाः (पूर्वपरायाः) सकाशाद्यथा दिग्गतस्य भुजस्याग्र शङ्कुमूलं बोध्यम् । छायाभुजकृतिविशेषमूलं (छायाभुजयोर्वर्गान्तरमूलं) यद् भवेत्तदेव छायाभुजाग्रयोर्नन्तरं प्राच्यपरा (पूर्वपरा) कोटिर्भवेदिति ॥५॥

अत्रोपपत्तिः

शङ्कुमूलात्पूर्वापररेखोपरिलम्बो भुज इत्येव दिग्मध्यगतस्य शङ्कोरछायाग्र-पूर्वापररेखयोर्नन्तरम्, दिग्मध्यगतशङ्कुच्छायाकर्णः, छायाग्रात्पूर्वापररेखोपरिलम्बो भुजः । भुजाग्रादिग्मध्यं (वृत्तकेन्द्रं) यावत्पूर्वापररेखायां कोटिः, ततः $\sqrt{\text{छाया}^2 - \text{भुज}^2} = \text{कोटिः}$, भास्कराचार्येणापि सिद्धान्तशिरोमणौ “दिक् सूत्रसम्पातगतस्य शङ्कोरछायाग्रपूर्वापरसूत्रमध्यमित्यादिना” तदेव कथ्यत इति ॥५॥

अब कोटि साधन को कहते हैं

वि. भा.—पूर्वापररेखा से भुजाग्र में शङ्कु मूल समझना चाहिये । छाया और भुज का वर्गान्तरमूल जो होता है वही छायाग्र और भुजाग्र का अन्तर पूर्वापरानकार कोटि होती है ॥५॥

उपपत्ति

शङ्कु मूल से पूर्वापररेखा के ऊपर लम्ब रेखा भुज है यही दिग्मध्य (वृत्तकेन्द्र) कक्षशङ्कु के छायाग्र और पूर्वापर रेखा का अन्तर है, दिग्मध्यगतशङ्कु छाया कर्ण, छायाग्र से

पूर्वापररेखा के ऊपर लम्बभुज, भुजाघ्र से दिग्मध्यपर्यन्त पूर्वापर रेखा में कोटि, इस जात्य त्रिभुज में $\sqrt{\text{छाया}^2 - \text{भुज}^2} = \text{कोटि}$, मास्कराचार्य ने भी सिद्धान्तशिरोमणि में “दिक्सूत्रसम्पातगतस्य शङ्कोरछायाग्रपूर्वापरसूत्रमध्यम्” इससे इसी बात को कहते हैं इति ॥ ५ ॥

इदानीं शङ्कुच्छायाग्रयोः स्थितिमाह

वि. भा.—विषुवति (विषुवद्दिने) मध्याह्नकाले शंकुरेव लम्बः (लम्बज्या) भवति तत्र या छाया साऽक्षज्या कल्पनीया, तद्वर्गसंयुतेर्मूलं विषुवत्कर्णो भवति, अन्यथाऽन्यस्मिन् दिने मध्याह्नादन्यस्मिन् काले वा शंकुना यः कर्णो भवति स द्वादशांगुलशंकोश्छायाकर्णो भवति, शंकुरित्यस्याग्रिमश्लोकेन सम्बन्ध इति ॥७॥

अत्रोपपत्तिः

सायनसूर्ये मेषादिगे मध्याह्ने द्वादशांगुलशंको या छाया सा पलभा (विषुवती), शंकुपलभयोर्वर्गयोगमूलं पलकर्णः (विषुवत्कर्णः) अक्षज्याभुजः । लम्बज्या कोटिः । त्रिज्याकर्णः इत्यक्षक्षेत्रसजातीयमेवापवर्त्तितं (पलभाभुजः । द्वादशांगुल-शङ्कुः कोटिः । पलकर्णः कर्ण इति भुजकोटिकर्णैरुत्पन्नं) लघुक्षेत्रमतोऽस्यकोटिभुजयोर्लम्बाक्षज्ये नामनी समुचिते एवेति ॥ ७ ॥

अब विषुवत्कर्ण को कहते हैं ।

हि. भा.—विषुवद्दिन में शंकु ही लम्बज्या होती है, वहां जो छाया होती है उसको अक्षज्या कल्पना करनी चाहिए, उन दोनों के वर्गयोग मूल विषुवत्कर्ण होता है, अन्य दिन (विषुवद्दिन से भिन्न दिन) में वा मध्याह्न काल से भिन्न काल में शंकुवश से जो कर्ण होता है वह द्वादशांगुल शंकु का छाया कर्ण होता है, 'शंकुः' इसका अगले श्लोक से सम्बन्ध है इति ॥ ७ ॥

उपपत्ति ।

सायन रवि जब मेषादि में रहते हैं तब मध्याह्न काल में द्वादशांगुलशंकु की जो छाया होनी है वह पलभा है, द्वादशांगुलशंकु और पलभा का वर्गयोग मूल पलकर्ण होता है, अक्षज्या भुज, लम्बज्या कोटि, त्रिज्या कर्ण इस अक्षक्षेत्र के सजातीय अपवर्त्तित (पलभा भुज, द्वादशांगुलशंकु कोटि, पलकर्ण कर्ण इन भुज कोटि कर्णों से उत्पन्न) लघु त्रिभुज है, इसलिये इसकी कोटि और भुज के नाम लम्बज्या और अक्षज्या समुक्ति ही है इति ॥ ७ ॥

इदानीं संज्ञा विशेषानाह -

वि. भा.—शंकुः उन्नत जीवा वा कोटिः छाया, दृग्ज्या नतज्या वतै शब्दा एक-पर्याया भुजः । यत्रैते भुजकोटी भवेतां तस्मिन् छायावृत्तोऽनयो (भुजकोटयोः) वंशेन यः कर्णस्तदेव व्यासार्धं (त्रिज्या) ज्ञेयम् । अतोऽन्यदत्रापि द्वयं ज्ञेयमर्थात् कोटिर्भुज-श्चेति यद्द्वयं तत्तायोर्वर्गयोगमूल व्यासार्धोत्पन्नवृत्तो कल्पनीयमिति ॥ ८ ॥

अब संज्ञा विशेष को कहते हैं ।

हि. भा.—शंकु वा उन्नतज्या कोटि, छाया, दृग्ज्या, वा नतज्या (ये एक पर्याय वाची शब्द हैं) भुज, जहां ये भुज और कोटि होती है, उस छायावृत्त में इन भुज और कोटि वश से जो कर्ण होता है वही व्यासार्धं (त्रिज्या) समझना चाहिये इससे अन्य अन्यत्र भी कोटि और

भुज ये दोनों जो हों उनको उन दोनों के वर्गयोग मूल व्यासार्धोत्पन्न वृत्त में कल्पना करना इति ॥ ८ ॥

इदानीं लम्बाक्षज्ययोरानयनमाह—

वि. भा.—शंकुशब्देनात्र द्वादशांगुलशंकुस्तथा छायाशब्देन पलभाया ग्रहणम् । द्वादशपलभयोर्वर्गयोस्त्रिज्यावर्गगुणितयोः तत्समासेन हृतयोः (द्वादशपलभयोर्वर्गयो-
गेन भक्तयोः) मूले तदा क्रमेण लम्बाक्षज्ये भवतः । तद्वनुभागाः (तयोश्चापांशः)
तदंशकाः (लम्बांशा अक्षांशाश्च) भवन्तीति ॥ ९ ॥

अत्रोपपत्तिः

$१२^२ + \text{पलभा}^२ = \text{पलकर्ण}^२$, $\frac{१२^२ \times \text{त्रि}^२}{\text{पलकर्ण}^२} = \text{लम्बज्या}^२ = \frac{१२^२ \times \text{त्रि}^२}{१२^२ + \text{पलभा}^२}$, तथा
 $\frac{\text{पलभा}^२ \times \text{त्रि}^२}{१२^२ + \text{पलभा}^२} = \text{अक्षज्या}^२$ एतयोर्मूले तदा लम्बाक्षज्ये भवतः । तयोश्चापे लम्बाक्षौ
भवेतामिति ॥ ९ ॥

अब लम्बज्या और अक्षज्या के साधन को कहते हैं ।

हि. भा.—शंकुशब्द से यहां द्वादशांगुलशङ्कु और छायाशब्द से पलभा का ग्रहण करना चाहिये, द्वादश वर्ग और पलभा वर्ग को त्रिज्या वर्ग से गुणा कर द्वादशवर्ग और पलभा वर्ग के योग से भाग देने से क्रमसे लम्बज्या और अक्षज्या होती है, दोनों के चाप करने से लम्बांश और अक्षांश होता है ॥ ९ ॥

उपपत्ति ।

द्वादशांगुलशंकु = कोटि, पलभा = भुज, पलकर्ण = कर्ण, } इन कोटि भुज कर्णों से उत्पन्न
लम्बज्या = कोटि, अक्षज्या = भुज, त्रिज्या = कर्ण, } अक्षक्षेत्र सजातीय हैं इसलिये
अनुपात करते हैं ।

$\frac{१२^२ \times \text{त्रि}^२}{\text{पलकर्ण}^२} = \text{लम्बज्या}^२$, तथा $\frac{\text{पलभा}^२ \times \text{त्रि}^२}{\text{पलकर्ण}^२} = \text{अक्षज्या}^२$, परन्तु $१२^२ + \text{पलभा}^२ =$

$\text{पलकर्ण}^२$, अतः उत्थापन देने से $\frac{१२^२ \times \text{त्रि}^२}{१२^२ + \text{पलभा}^२} = \text{लम्बज्या}^२$, $\frac{\text{पलभा}^२ \times \text{त्रि}^२}{१२^२ + \text{पलभा}^२} = \text{अक्षज्या}^२$, दोनों
के मूल लेने से लम्बज्या और अक्षज्या होती है, चाप करने से लम्बांश और अक्षांश होता है
इति ॥ ९ ॥

इदानीं प्रकारान्तरेण तयोरानयनमाह—

वि. भा.—त्रिज्ये पृथक् शंकुच्छाया हते (द्वादश पलभागुणिते) विषुवत्कर्णहते
(पलकर्णभक्ते) लम्बाक्षज्ये भवतः । वा लम्बाक्षांशोत्क्रमज्योने त्रिज्ये अक्षज्येतर-

जीवे (अक्षज्यालम्बज्ये) भवनोऽर्थान्तरम्बांशोत्क्रमज्यानां त्रिज्याऽक्षज्या, अक्षांशो-
त्क्रमज्यानां त्रिज्या लम्बज्या भवतीति ॥ १० ॥

अत्रोपपत्तिः

पूर्वश्लोके वर्गानुपातेन लम्बाक्षज्ययोर्वर्गवानोय तन्मूलेन लम्बाक्षज्ये समा-
नीते, अत्रमाधारणानुपातेन तयोरानयनमस्मिन् त्रि—लम्बांशोत्क्रमज्या=अक्षज्या,
त्रि—अक्षांशोत्क्रमज्या=लम्बज्या, सिद्धान्तशेखरे 'लम्बाक्षभागोत्क्रममार्जिजनी या
तया त्रिमोर्वी रहितेतरा वा' इत्यनेन श्रीपतिना, 'ये दोः कोट्योस्तः क्रमज्ये तदूने
त्रिज्ये ते वा कोटिदोरुत्क्रमज्ये' इति विलोमेन भास्करेणापि तदेव कथ्यत इति ॥१०॥

अब प्रकारान्तर से उन दोनों (लम्बज्या और अक्षज्या) के मापन को कहते हैं ।

हि. भा.—त्रिज्या को पृथक् द्वादश से और पलभा से गुणा कर पलकरण से भाग देने
से लम्बज्या और अक्षज्या होती है, वा त्रिज्या में लम्बांश की उत्क्रमज्या को घटाने से अक्षज्या
होती है, तथा त्रिज्या से अक्षांशोत्क्रमज्या को घटाने से शेष लम्बज्या होती है इति ॥१०॥

उपपत्ति ।

पहले के श्लोक में वर्गानुपात से लम्बज्यावर्ग और अक्षज्यावर्ग लाकर मूल लेकर
लम्बज्या और अक्षज्या लाये हैं, यहां साधारण अनुपात से उन दोनों का आनयन है, त्रि—लम्बां-
शोत्क्रमज्या=अक्षज्या, त्रि—अक्षांशोत्क्रमज्या=लम्बज्या, सिद्धान्त शेखर में 'लम्बाक्षभा-
गोत्क्रममार्जिजनी या' इत्यादि से श्रीपति तथा 'ये दोः कोट्योस्तः क्रमज्ये तदूने त्रिज्ये ते वा
कोटिदोरुत्क्रम ज्ये' इसके विलोम से भास्कराचार्य भी इसी बात को कहते हैं इति ॥ १० ॥

पुनः प्रकारान्तरेण लम्बाक्षज्ये आह—

लम्बाक्षांशान् नवतेः प्रोह्य (हित्वा) ज्या साध्या तदा वा (प्रकारान्तरेण)
इतरा ज्या स्यादर्थांल्लम्बांशोननवतेज्याऽक्षज्या, अक्षांशोननवतेज्या लम्बज्या,
अक्षलम्बज्ये-शंकुज्जायागुणिते (द्वादशपलभागुणिते) छायाद्वादशहते (पलभा
द्वादश भक्ते) तदा वा (प्रकारान्तरेण) अन्ये लम्बाक्षज्ये भवत इति ॥११॥

अत्रोपपत्तिः ।

ज्या (१०—अक्षांश) = लम्बज्या, ज्या (१०—लम्बांश) = अक्षज्या, वा
 $\frac{\text{अक्षज्या} \times १२}{\text{पलभा}} = \text{लंज्या}$, तथा $\frac{\text{पभा} \times \text{लंज्या}}{१२} = \text{अक्षज्या}$, एतावताऽऽचार्यो-
क्तमुपपद्यते ॥ ११ ॥

अब पुनः प्रकारान्तर से लम्बज्या और अक्षज्या को कहते हैं ।

हि. मा.—नवत्यंश में से लम्बांश को घटाने से शेष की ज्या अक्षज्या होती है, नवत्यंश में से अक्षांश को घटाने से शेष की ज्या लम्बज्या होती है, वा अक्षज्या और लम्बज्या को क्रम से द्वादश और पलभा से गुणाकर पलभा और द्वादश से भाग देने से लम्बज्या और अक्षज्या होती है इति ॥११॥

उपपत्ति

ज्या (९०—अक्षांश) = लम्बज्या, ज्या (९०—लम्बांश) = अक्षज्या, वा
 $\frac{\text{अक्षज्या} \times १२}{\text{पलभा}} = \text{लंज्या}, \frac{\text{पभा} \times \text{लंज्या}}{१२} = \text{अक्षज्या}$ इससे आचार्योक्त उपपन्न
 हुआ ॥११॥

इदानीं पुनः प्रकारान्तरेणाह —

वि. मा.—त्रिज्याकृतेः (त्रिज्यावर्गात्) लम्बाक्षज्यावर्गं प्रोह्य पदं वाज्या
 (त्रिज्यावर्गाल्लम्बज्यावर्गं विशोध्यमूलमक्षज्या तथा त्रिज्यावर्गाक्षज्यावर्गं
 विशोध्य मूलं ग्राह्यं वाज्या लम्बज्या) भवेत् । एवमन्त्यत्र सर्वदोन्तनतजीवांशा-
 नयनं कार्यमर्थान् नतज्या वर्गोनात् त्रिज्यावर्गान्मूलमुन्नतज्या, उन्नतज्यावर्गोनात्
 त्रिज्यावर्गान्मूलं नतज्या भवेत् । एतयोश्चापे उन्नतांशा नतांशाश्च भव-
 न्तीति ॥१२॥

अत्रोपपत्तिः ।

$\sqrt{\text{त्रि}^2 - \text{लंज्या}^2} = \text{अज्या}, \sqrt{\text{त्रि}^2 - \text{अज्या}^2} = \text{लंज्या}, \text{नतांशज्या} = \text{दृग्ज्या},$
 $\text{उन्नतांशज्या} = \text{शंकुः}, \sqrt{\text{त्रि}^2 - \text{शंकु}^2} = \text{दृग्ज्या}, \sqrt{\text{त्रि}^2 - \text{दृग्ज्या}^2} = \text{शंकुः},$
 इति ॥१२॥

अब पुनः प्रकारान्तर से लम्बज्या और अक्षज्या को कहते हैं ।

हि. मा.—वा त्रिज्यावर्ग में से लम्बज्यावर्ग को घटाने से शेष का मूल अक्षज्या होती है, त्रिज्यावर्ग में से अक्षज्यावर्ग को घटाने से शेष का मूल लम्बज्या होती है, इसी तरह उन्नतांशज्या और नतांशज्या का आनयन करना अर्थात् नतांशज्यावर्ग को त्रिज्यावर्ग में से घटाने से शेष का मूल उन्नतांशज्या (शङ्कु) होती है, तथा उन्नतांशज्यावर्ग को त्रिज्यावर्ग में से घटाने से शेष का मूल नतांशज्या (दृग्ज्या) होती है, इन दोनों का बाप उन्नतांश और नतांश होता है । इति ॥१२॥

उपपत्ति

$\sqrt{\text{त्रि} - \text{नग्या}} = \text{अग्या}$, तथा $\sqrt{\text{त्रि} - \text{अग्या}} = \text{नग्या}$, $\sqrt{\text{त्रि} - \text{उन्ननाग्या}} = \sqrt{\text{त्रि} - \text{गङ्गा}} = \text{दृग्या}$, $\sqrt{\text{त्रि} - \text{ननाग्या}} = \sqrt{\text{त्रि} - \text{दृग्या}} = \text{गङ्गा}$ इति ॥१२॥

इदानीं दिनार्धे नतांशं क्रान्त्यंशजाने मन्यक्षांशजानमाह ।

अब स्वदेशोदय साधन को कहते हैं ।

हि. भा.—पूर्व प्रकार से ध्याये हुए मेपादि तीन राशियों के निरक्षोदयमानों को क्रम
से और उत्क्रम (विसोम) से स्थापित करना वया क्रम क्रमस्थित और उत्क्रमस्थित अपनी
चरामु को हीन और युत करने से मेपादि छः राशियों के स्वदेशोदयामुमान होते हैं ; इतने
ही विपरीत तुलादि छः राशियों के स्वदेशोदयामु मान होते हैं ; ‘अर्कं तात्कालिकं कृत्वा’
इसका ध्याये से सम्बन्ध है इति ॥ १७ ॥

उपपत्ति

निरक्षार्कोदय और स्वदेशार्कोदय का अन्तर चर है, अपने देश में और निरक्ष देश में
मेपादिबिन्दु एक ही काल में उदित होता है, मेपान्तबिन्दु पहले अपने क्षितिज में आता है
उसके बाद चरखण्ड कालान्तर में उन्मराहण में आता है इसलिए निरक्षदेशीय मेपोदयमान
में से चरखण्ड को घटाने से स्वदेशीय मेपोदयमान होता है, इसी तरह वृष और मिथुन का जी
होता है, कर्वादि में चरखण्डों के अपचीयमानत्व (ह्रासत्व) के कारण बन होते हैं ।

तुलादियों में अपने क्षितिज से उन्मण्डल के नीचा रहने के कारण चरखण्ड घन होते हैं । मकरादियों में चरखण्डों के अपचीयमानत्व के कारण श्रृण होते हैं, सिद्धान्त शिरोमणि में भास्कराचार्य भी “क्रमोत्क्रमस्थाश्चरखण्डकैः” इत्यादि संस्कृतोपपत्ति में लिखित श्लोक से आचार्योक्तानुरूप ही कहते हैं इति ॥ १७ ॥

पुस्तकमवलोकनीयमिति ॥१८-१९-२०॥

अब स्वदेश में लग्नानयन को कहते हैं ।

हि. भा.—रवि को तात्कालिक करके उनकी राशिभोग्यकला को स्वोदयासु (जिस
राशि में रवि है, उसके स्वदेशोदयासु) से गुणा कर राशिकला से भाग देने से जो अस्वात्मक
लब्धि हो उसको डटकालासु में से घटा देना, राशि के भोग्यांश को रवि में जोड़कर शेषासु
में क्रम से जितने राश्युदयासु घटे उतनी राशि सूर्य में जोड़ देना, शेष को तीस से गुणा कर
अशुद्धोदय (जिस राशि का उदयासु मान नहीं घटा है उससे) से भाग देकर जो अंशादिक
लब्धि हो उसको रवि में जोड़ देना ऐसा करने से लग्न होता है इति ॥ १८-१९-२० ॥

उपपत्ति

उदयक्षितिज में क्रान्तिवृत्त का जो बिन्दु लगा है अर्थात् उदयक्षितिज और क्रान्तिवृत्त
का सम्पात बिन्दु लग्न है, जिस राशि में तात्कालिक रवि है उस राशि की भोग्यकला से
अनुपात करते हैं यदि राशिकला में उस राशि के स्वोदयासुमान पाते हैं तो रवि भोग्यकला
में क्या इससे रवि का भोग्यासु प्रमाण आता है, इसको डटकालासु (रविभोग्यासु, लग्नभुक्त, सु
और रविलम्बान्तरालोदयासुओं के योग) में से घटा देना तब जो शेष रहे उसमें जितने राश्यु-
दयमान घटे उन्हें घटा देना । शेष से अनुपात ‘यदि अशुद्धराश्युदयासु में तीस अंश पाते हैं तो
शेषासु में क्या’ से जो अंशादिक फल आता है उसमें मेषादि से अशुद्ध राशि से अव्यवहित पूर्व
राशितक राशि संख्या जोड़ने से लग्न होता है । परन्तु राशियों के स्थूलत्व के कारण उनका
उदयमान भी स्थूल होता है, सब प्राचीनाचार्यों ने स्थूल राश्युदयमान ही के वस से लग्ना-
नयन किया है इसीलिये वह ठीक नहीं है, अतः सिद्धान्त शिरोमणि की टिप्पणी में संशोधक
(वापूदेव शास्त्री) ने शुद्ध लग्नानयन किया है । लेकिन वह भी ठीक नहीं है, महामहोपाध्याय
पण्डित सुधाकर द्विवेदी ने उसका सम्मन्धन किया है । और ‘आकाशमध्य विषुवांशवजात्प्रकुर्याद्’
इत्यादि संस्कृतोपपत्ति में लिखित श्लोकों से अपना शुद्ध लग्नानयन प्रकार किया है; सूर्य

मिद्धानकार इहो गुण्य आदि प्राचीनाचार्यों ने निर्यगगवि ही में लग्नानयन किया है जो उचित नहीं है, सायन रवि में लग्नानयन करना समुचित है जैसा कि बहुत प्राचार्यों ने किया है, मैंने छः प्रकार में अपूर्व लग्नानयन किया है उसके लिये मेरी 'लग्नानयनम्' पुस्तक को देखिये । इति ॥ १८-१९-२० ॥

हि. भा.—पूर्व इत्येवं तात्कालिक सूर्य और इष्ट कास जान कर लग्न कलाया भव

है अब इस ग्रन्थ से तात्कालिक के रवि और लग्न ज्ञात करके इष्ट काल बनाते हैं ।

गोल युक्ति से तात्कालिक रवि केन्द्र के ऊपर जो अहोरात्र वृत्त होता है, उसमें क्षिति-जपर्यन्त इष्टकाल कहा गया है, इस इष्ट काल में उदयक्षितिज से ऊपर सूर्य के रहने पर रवि के भोग्यासु, लग्न के भुक्तासु और तदन्तर्गत राशियों का उदयासु, इन सबों का योग है । अत एव आचार्य कहते हैं कि रवि के भोग्यांश को वर्तमान राश्युदय से गुणा कर राशि-कला (१८००) से भाग देकर जो लब्धि आया वह रवि के भोग्यासु हैं, उसमें लग्न के भुक्तानु अर्थात् लग्न के भुक्तांश को राश्युदय से गुणा कर राशि कला से भाग देकर लब्धि तुल्य रवि के पूर्वानीत भोग्यासु में जोड़ते हैं, और अन्तरवर्ती राशियों का उदयासु जोड़कर सावनेष्ट घटी आचार्य बनाते हैं, परंच सावनेष्ट घटी चल है इसलिये आचार्य यहां असकृत् कर्म करते हैं ।

आचार्य का सकृत् कर्म कहने का तात्पर्य यह है कि नाक्षत्रेष्ट घटी ज्ञात नहीं है, ज्ञान है सावनेष्ट घटी अत एव उक्त प्रकार द्वारा नाक्षत्रेष्ट घटी ज्ञात नहीं होगी । इसलिए सकृत् क्रिया द्वारा इष्ट घटी स्थिर की जाती है । भास्कराचार्य भी कहते हैं कि “लग्नार्थमिष्टघटिका यदि सावनास्ताः तात्कालिकार्ककरेण भवेयुराक्षयः” का गोलाध्याय में विशेष वर्णन है ॥ २१-२२-२३ ॥

वि. भा.—प्रश्नासुभिः प्राक् (पूर्व) उदये (लग्ने) अपेक्षिते भुक्तराशिभिः (भुक्तांशैर्भुक्तराशिभिश्च) अर्कः (रविः) ऊनः (हीनः) तदा लग्नं भवेत् । लग्नात्कालानयने चार्कलग्नसममूनं कृत्वा एवं प्राक् (सूर्योदयात्पूर्व) इष्टकालो भवेत् । एतदुक्तं भवति तात्कालिकरवेर्भुक्तांशादिकं रव्याकान्तं राश्युदयमानेन सङ्गुण्य त्रिंशद्भिर्भक्ता लब्धमिष्टासुभ्यो विशोध्य रवेश्च राशिभुक्तं शोधयेत् । शेषासुभ्योऽपि यावन्तो राशयोऽभुक्ताः शोधयितुं शक्यन्ते तेषामसून् विशोध्य रवावपि तावन्तो राशयः शेषासूश्च त्रिंशता संगुण्यागुद्वाराश्युदयेन विभज्य लब्धमंशादिकं रवेः शोधयं तदा रात्रिशेषे लग्नं भवति । एवमानीताद्वारात्रिशेषलग्नात्कालानयनार्थं यथापूर्वकालेन हीनो रविः स्वदेशराश्युदयलब्धराश्यंशादिभिर्लग्नत्वं प्रापितः एवं वैपरीत्येन लग्नस्य समतां नीते सति तस्मिन् रवौ रात्रिशेषगतकालः स्पष्टो भवति । एतदुक्तं भवति, लग्नादभुक्तांशैरन्तरराश्युदयैश्च संमितैरमकृत्कर्मणा रात्रिशेषे स्फुटः कालो भवति । रविरभुक्तांशराश्यादिरहितो लग्नसमो भवतीति ॥ २४ ॥

अत्रोपपत्तिरपि भाष्यरूपैव बोध्या । सिद्धान्तशेखरे 'प्रागुदयमादपि रविर्गत-राशिभागैः प्राग्भोदयैर्विरहितश्च विलग्नमेवमूने रवौ तनुसमे च कृते स कालः' श्रीपत्युक्तमिदं शिरोमणौ 'भुक्तासुशुद्धे विपरीतलग्नमित्यादि' भास्करोक्तं चाऽऽचार्योक्तानुरूपमेवेति ॥ २४ ॥

अब विलोमलग्न को तथा उससे कालानयन को कहते हैं ।

हि. भा.—इष्टासु से पूर्व लग्न अपेक्षित हो तो भुक्तांश और भुक्तराशियों को रवि में से घटाने से लग्न होता है, तात्कालिक रवि के भुक्तांशादि का जिस राशि में रवि हो उस राशि के उदय मान से गुणाकर तीस से भाग देकर जो लब्धि हो उसको इष्टासु में से घटा कर सूर्य में से भी राशिभुक्त को घटा देना चाहिए । शेषासु में जितनी अभुक्त राश्युदयमानासु घट सके उन्हें घटा कर रवि में से भी उतनी राशियां घटा देना, शेषासु को तीस से गुणाकर अभुद्धराशि के उदयमान से भाग दे कर जो अंशादिक लब्धि हो उसको रवि में से घटाने से रात्रि शेष में लग्न होता है । इस तरह लाए हुए रात्रि शेष लग्न से अभुक्तांश और रवि तथा लग्न के अन्तर में जो राशियां हैं उनके उदयमानों के योग से असकृत् कर्म से रात्रि शेष में स्फुट इष्टकाल होता है ॥ २४ ॥

इसकी उपपत्ति भाष्य रूप ही है । सिद्धान्त शेखर में "प्रागुदयमादपि रविर्गत-राशिभागैः इत्यादि संस्कृतोपपत्ति में लिखित श्लोक से, उपपत्ति तथा सिद्धान्त शिरोमणि में "भुक्तासु शुद्धे विपरीतलग्नं" इत्यादि से भास्कराचार्योक्त के अनुरूप ही कहा है इति ॥ २४ ॥

वि. भा.—दृग्ज्या द्वादशांगुलशंकुना शंकुना विभाजिता (भक्ता) फलं छाया
भवेत् । व्यासार्धं (त्रिज्या) विषुवत्कर्णा हनं (फलकर्णगुणितं) छेदहृतं (हनिभक्तं) ।
तदा कर्णः (छायाकर्णः) भवेदिति ॥२८॥

अत्रोपपत्तिः ।

छाया = भुजः । द्वादशांगुलशंकुः = कोटिः । छायाकर्णः = कर्णः । } अनयोगेच्छाया-
दृग्ज्या = भुजः । दृष्टशंकुः = कोटिः । त्रिज्या = कर्णः ।

क्षेत्रयोः मजानीयन्वादनुपातो यदि शंकुना दृग्ज्या लभ्यते तदा द्वादशांगुलशंकुना
किं समागच्छति छाया = $\frac{\text{दृग्ज्या} \times १२}{\text{शंकु}}$, तथा यदि शंकुना त्रिज्या लभ्यते तदा

द्वादशांगुलशंकुना किं समागच्छति छायाकर्णः = $\frac{\text{त्रि} \times १२}{\text{शंकु}}$, परन्तु $\frac{१२ \times \text{हनि}}{\text{फल}} =$

शंकुः, अनेन शंकोरुत्थापनेन छायाकर्णः = $\frac{\text{त्रि} \times १२}{१२ \times \text{हनि}} = \frac{\text{त्रि} \times \text{फल}}{\text{हनि}}$ एतेनाऽऽचार्यो-

क्तमुपपद्यते, श्रीपतिना 'व्यासदले विषुवच्छत्राघ्ने छेदहृते यदि वेप्सितकर्णः' ।
ऽप्यनेनाऽऽचार्योक्तमेव कथ्यते, पूर्वानुपातद्वयेन समागते छाया-छाया कर्णो एव
'दृग्ज्या त्रिजीवे रविसंगुणेति शङ्कदधृते भाश्रवणी भवेतामिति भास्करोक्तं
इति ॥२८॥

अब छाया और कर्ण को कहते हैं ।

हि. भा.—दृग्ज्या को बारह से गुणा कर शंकु से भाग देने से छाया होती है, त्रिज्या
को फलकर्ण से गुणा कर छेद (दृष्टहति) से भाग देने से छाया कर्ण होता है इति ॥ २८ ॥

उपपत्ति ।

छाया = भुज, द्वादशांगुल शंकु = कोटि, छायाकर्ण = कर्ण } ये दोनों छाया क्षेत्र मजानीय है
दृग्ज्या = भुज, दृष्टशंकु = कोटि, त्रिज्या = कर्ण }
इसलिये अनुपात करते हैं । यदि शंकु में दृग्ज्या पाते हैं तो द्वादशांगुल शंकु में क्या इससे छाया
प्राप्ती है $\frac{\text{दृग्ज्या. १२}}{\text{शंकु}} = \text{छाया}$, तथा यदि शंकु में त्रिज्या पाते हैं तो द्वादशांगुल

शंकु में क्या इससे छायाकर्ण प्राप्ती है $\frac{\text{त्रि. १२}}{\text{शंकु}} = \text{छायाकर्ण}$, परन्तु $\frac{१२ \times \text{हनि}}{\text{फल}}$

= शंकु, इससे शंकु को उत्थापन देने से $\frac{\text{त्रि. १२}}{१२ \times \text{हृति}} = \frac{\text{हृति}}{१२}$ = छायाकर्ण = $\frac{\text{त्रि. एक}}{\text{हृति}}$ इससे आचा-

र्योक्त उपपन्न होता है। सिद्धान्त शेखर में श्रीपति भी 'व्यासदले विषुवच्छ्वरणे छेदहृते यदि वेप्सितकर्णः' इससे आचार्योक्त ही को कहते हैं, पहले अनुपात द्वय से आई हुई छाया और छायाकर्ण ही को 'दृज्या त्रिजीवे रविसंगुणे ते शंकूदृते भाश्वरणी भवेताम्' से भास्क-राचार्य भी कहते हैं इति ॥ २८ ॥

वि. भा.—सप्तदिवसोर्मेष्यान्ध्रकान्तिकरिज्यान्वयासोर्वो गो विन्ददिवस-

योस्तयोरन्तरं तदा मध्याह्ने नतांशा भवन्ति, नवतेर्नतांशान् विशोध्य शेषा उन्नतांशा बोध्या इति॥४७॥

अत्रोपपत्तिः

यदि मध्याह्नकाले खस्वस्तिकनिरक्षस्वस्तिकयोर्मध्ये याम्योत्तरवृत्ते रविस्तदा रवितो निरक्षस्वस्तिकं यावद्रविक्रान्तिः । खस्वस्तिकनिरक्षस्वस्तिकयोरन्तरमक्षांशा अत्र द्वयोरन्तरेण विनतांशा रवितः खस्वस्तिकं यावत् । यदि च निरक्षस्वस्तिकाद् दक्षिणे रविस्तदा रवितो निरक्षस्वस्तिकं यावत्क्रान्तिः । अत्राक्षांशरविक्रान्तयोः समदिक्कयो (अक्षांशाः सर्वदा दक्षिणा, नाडीवृत्ताद्रविर्दक्षिणेऽस्त्यतः क्रान्तेरपि दिक्दक्षिणा) योगेन रविमध्यनतांशा भवन्ति, खस्वस्तिकात्समस्थानं यावन्नवतिरत्र नतांशशोधनेन रवितः समस्थानं यावन्मध्योन्नतांशाः स्युः । सिद्धान्तशेखरे “मध्यन्दिनोष्णकिरणापमचापभागस्वाक्षांशयोगविवरं सदृशान्यदिक्त्वे । याम्योत्तरा नतलवास्तरणोः खमध्यात् तेऽप्युन्नता निपतिता नवतेर्भवेयुरिति” श्रौपत्युक्तं सिद्धान्तशिरोमणी “पलावलम्बावपमेन संस्कृतौ नतोन्नते ते भवतो दिवादले लवादिकं वा नवतेर्विशोधितं नतं भवेदुन्नतमुन्नतं नतम्” इतिभास्करोक्तञ्चाऽऽचार्योक्तानुरूपमेवेति ॥४७॥

अब मध्याह्नकालिक नतांश और उन्नतांश साधन को कहते हैं

हि. भा.—एक दिशा में रविमध्यक्रान्ति और अक्षांश का योग करने से और भिन्न दिशा में अन्तर करने से रवि का मध्यनतांश होता है, नतांश को नवत्यंश में घटाने से शेष उन्नतांश होता है इति ॥४७॥

उपपत्ति

मध्याह्नकाल में यदि खस्वस्तिक और निरक्षस्वस्तिक के मध्य में रवि है तब रवि से निरक्ष खस्वस्तिक पर्यन्त रवि की मध्यक्रान्ति उत्तर दिशा को है क्योंकि नाडीवृत्त से रवि उत्तर में है, तथा अक्षांश की दिशा सर्वदा दक्षिण है इसलिये भिन्न दिशा की रविक्रान्ति और अक्षांश का अन्तर करने से रवि से खस्वस्तिक पर्यन्त रवि का नतांश होता है, यदि निरक्ष खस्वस्तिक से रवि दक्षिण है, तब अक्षांश और क्रान्ति की दिशा एक ही दक्षिण होने के कारण दोनों का योग करने से नतांश होता है, खस्वस्तिक से समस्थान तक नवत्यंश में नतांश को घटाने से निरक्षखस्वस्तिक से समस्थानपर्यन्त मध्य उन्नतांश होता है, सिद्धान्तशेखर में “मध्यन्दिनोष्णकिरणापमचापभागस्वाक्षांशयोगविवरं” इत्यादि संस्कृतोपपत्ति में विहित श्लोक से श्रौपति तथा सिद्धान्तशिरोमणि में “पलावलम्बावपमेन संस्कृतौ” इत्यादि संस्कृतोपपत्ति में विहित श्लोक से भास्कराचार्य ने भी आचार्योक्तानुरूप ही कहा है इति ॥४७॥

वि. भा.—नतभागज्या (नतांशज्या हज्या) द्वादशगुणिता, उन्नतांशज्या (शङ्कुना) भक्ता लघ्वमिष्टदिनार्धच्छाया भवति, वा दिनार्धात् सकाशाद्योक्त-करणहृत्यादिभिर्दिनार्धच्छाया साध्येति ॥४८॥

अत्रोपपत्तिः

हज्या भुजः । शङ्कुः कोटिः । त्रिज्याकर्णः
छायाभुजः । द्वादशाङ्गुलशङ्कुः कोटिः । छायाकर्णः कर्णः }

एतयोस्त्रिभुजयोः साजात्यादनुपातः

$\frac{\text{हज्या. १२}}{\text{शङ्कु}} = \text{छाया.}$ सिद्धान्तशेखरे 'ना शङ्कुरन्नतगुणः स च कोटिरुक्ता

हज्या भुजा नतगुणस्तु भवेत् प्रभा च । अर्कपर्वतितनरेण हूते च हज्या त्रिज्ये दले दिनदलोत्थविभा श्रुती च" श्रोपत्युक्तमिति छायासाधनं, सिद्धान्त-शिरोमणी 'हज्या त्रिजीवे रविसङ्गुणे ते शङ्कुदुधूते भाश्रवणी भवेताम्' भास्करोक्तं छायासाधनञ्चाऽऽचार्योक्तानुरूपमेवेति ॥४८॥

अब इष्ट दिनार्ध में छायापानयन को कहते हैं

हि. भा.—नतांशज्या (हज्या) को बारङ् से गुणा कर शङ्कु से भाग देने से लब्धि इष्टदिनार्धकालिक छाया होती है, वा दिनार्ध से पूर्वकक्षितोपकरणों (हृति आदि) से दिनार्धच्छाया साधन करना इति ॥४८॥

उपपत्ति

हज्या भुज, शङ्कु कोटि, त्रिज्या कर्ण
छाया भुज, द्वादशाङ्गुलशङ्कु कोटि, छायाकर्ण. कर्ण }

ये दोनों त्रिभुज सजातीय हैं इसलिए अनुपात करते हैं

$\frac{\text{हज्या. १२}}{\text{शङ्कु}} = \text{छाया,}$ सिद्धान्तशेखर में 'ना शङ्कुरन्नतगुणः' इत्यादि संस्कृतोपपत्ति

में लिखित प्लोक से उपपत्ति तथा सिद्धान्त शिरोमणि में "हज्या त्रिजीवे" इत्यादि से भास्कराचार्य ने भी छायासाधन आचार्योक्तानुरूप ही कहा है इति ॥४८॥

वि. भा.—व्यासार्ध (त्रिज्या) द्वादशगुणितं, उन्नतजीवा (मध्यशङ्कु) भक्तं तदा मध्यच्छायाकर्णो भवेत् । कर्णद्वादशगुण्यन्तरपदं (छायाकर्णद्वादश-वर्गान्तरमूल) वा (प्रकारान्तरेण) मध्यच्छाया भवेदिति ॥४९॥

अत्रोपपत्तिः

छायाक्षेत्रानुपातेन $\frac{\text{त्रि.१२}}{\text{शङ्कु}} = \text{छायाकरणं ततः } \sqrt{\text{छायाक}^2 - १२^2} = \text{छाया,}$
इति ॥४९॥

अब प्रकारान्तर से मध्यच्छायानयन को कहते हैं

हि. भा.—त्रिज्या को बारह से गुणा कर मध्यशङ्कु से भाग देने से मध्यच्छाया करण होता है, छायाकरण और द्वादश (१२) क वर्गान्तर मूल प्रकारान्तर से मध्यच्छाया होती है इति ॥४९॥

उपपत्ति

पूर्व श्लोक की उपपत्ति में प्रदर्शित छायाक्षेत्रों के सजातीयत्व से अनुपात करते हैं

$\frac{\text{त्रि.१२}}{\text{मध्यकु}} = \text{मछायाकरणं, } \therefore \sqrt{\text{छायाक}^2 - १२^2} = \text{मध्यच्छाया, इति ॥४९॥}$

वि. भा.—यथोक्तकरणैः (दिनगतशेषाल्पस्येत्यादिप्रकारैः) मध्याह्ने द्युदलान्त्या (हृतिः), ज्या (इष्टान्त्या) छेदः (इष्टहृतिः) मध्यच्छाया प्रसिद्धा, इति सर्वं वा भवति, अथवा—अन्त्या ज्या छेदाद्यैः (अन्त्येष्टान्त्येष्टहृत्यादिभिः) पूर्व कथितविधिनाऽनेकधा मध्यच्छाया साध्येति ॥५०॥

अत्रोपपत्तिस्तु श्लोकोक्तोपकरणैर्बोध्येति ॥५०॥

अब हृति आदियों के बहुसाधनत्व को कहते हैं

पूर्व कथित उपकरणों (दिनगतशेषाल्पस्य इत्यादि प्रकार से) से मध्याह्नकाल में हृति, इष्टान्त्या, छेद (इष्टहृति) मध्यच्छाया ये सब होते हैं। अथवा अन्त्या, ज्या (इष्टान्त्या) छेद (इष्टहृति) आदि से पूर्व कथित विधि से अनेक प्रकार मध्यच्छाया साधन करना इति ॥५०॥

उपपत्ति

श्लोक में कथित उपकरणों से अनेक प्रकार मध्यच्छायानयन करना चाहिए इति ॥५०॥

इदानीं समशङ्कुसाधनमाह

अब कोणशङ्कु के मानयन को कहते हैं

हि. भा.—त्रिज्या वर्गाधर्म में रवि की अग्रावर्ग घटाकर बाहर के वर्ग से गुणा कर
जो हो उसका नाम आद्य है, अग्रा, द्वादश, और पलभा के घात का नाम अन्य है,
पलभावर्ग में बहत्तर (७२) जोड़कर आद्य और अन्य में भाग देने से विशिष्ट आद्य और
अन्य होता है, आद्य (विशिष्ट आद्य) में अन्य (विशिष्ट अन्य) वर्ग जोड़कर मूल लेना,
उसमें अन्य (विशिष्ट अन्य) को जोड़ना और घटाना तब उत्तरगोल में और दक्षिण
गोल में कोणशङ्कु होता है । शेष की व्याख्या स्पष्ट है इति ॥५४-५५-५६॥

उपपत्ति

कोणवृत्तस्थ रवि से क्षितिजधरातल के ऊपर जो सम्ब होता है उसका नाम
कोणशङ्कु है, उसके मूल से पूर्वपर रेखा के ऊपर सम्ब भुज संज्ञक है, भुजमूल से दूकेन्द्र
पर्यन्त वा कोणशङ्कु मूल से शान्योत्तर रेखा के ऊपर सम्ब कोटि संज्ञक है, दूकेन्द्र से
कोणशङ्कुमूलपर्यन्त दृग्ज्याकर्ण, भुज-भुज, कोटि-कोटि इस त्रिभुज में कर्ण और कोटि
से उत्पन्न कोण = ४५° इसलिये कर्ण और भुज से उत्पन्न कोण भी = ४५° अतः भुज
= कोटि इसलिये २यु° = दृग्ज्या°, वहां कल्पना करते हैं कोणशङ्कु प्रमाण = य, तब
अनुपाय से शङ्कुतल = $\frac{पलभा-य}{१२}$, अग्रा और शङ्कुतल के संस्कार से उत्तरगोल में और

दक्षिणगोल में क्रम से मुख = $\frac{\text{पमा} \cdot \text{य}}{१२}$, यहां $\text{य} = \text{अमा}$ । मुखवर्ग = $\left(\text{य} + \frac{\text{पमा} \cdot \text{य}}{१२} \right)^2$

$$= \text{य}^2 + \frac{२ \text{य} \cdot \text{पमा} \cdot \text{य}}{१२} + \frac{\text{पमा}^2 \cdot \text{य}^2}{१४४} \text{ द्विगुणित करने से } २ \text{यु}^2 = \text{ह्यग्या}^2 = \text{त्रि}^2 - \text{य}^2$$

$$= \frac{१४४ \text{य}^2 + २४ \text{य} \cdot \text{पमा} \cdot \text{य} + \text{पमा}^2 \cdot \text{य}^2}{७२} \text{ छेदगम और समसोचन से } (\text{पमा}^2 + ७२) \text{य}^2 +$$

$$२४ \text{य} \cdot \text{पमा} \cdot \text{य} = ७२ \text{ त्रि}^2 - १४४ \text{य}^2 = १४४ \left(\frac{\text{त्रि}^2}{२} - \text{य}^2 \right) \text{ दोनों पक्षों में } (\text{पमा}^2 + ७२)$$

$$\text{इससे भाग देने से य}^2 + \frac{२४ \text{य} \cdot \text{पमा} \cdot \text{य}}{\text{पमा}^2 + ७२} = \frac{१४४ \left(\frac{\text{त्रि}^2}{२} - \text{य}^2 \right)}{\text{पमा}^2 + ७२} \text{ यहाँ } १४४ \left(\frac{\text{त्रि}^2}{२} - \text{य}^2 \right)$$

$$= \text{भाष संज्ञक, } १२ \cdot \text{य} \cdot \text{पमा} = \text{अन्यसंज्ञक, तब य}^2 + \frac{२ \text{अन्य}}{\text{पमा}^2 + ७२} = \frac{\text{भाष}}{\text{पमा}^2 + ७२}$$

$$= \text{य}^2 + २ \text{अन्य} = \text{भाष} \text{ दोनों पक्षों में अन्य}^2 \text{ जोड़ने से य}^2 + २ \text{अन्य} + \text{अन्य}^2 = \text{भाष}^2$$

$$+ \text{अन्य}^2 \text{ मूल लेने से य} + \text{अन्य} = \sqrt{\text{भाष}^2 + \text{अन्य}^2} \therefore \text{य} = \sqrt{\text{भाष}^2 + \text{अन्य}^2} \pm \text{अन्य}$$

इससे भाचार्योक्त उपपन्न हुआ। जब $\frac{\text{त्रि}^2}{२} < \text{य}^2$ तब उत्तरगोल में भाष का मान ऋण

होने से चार कोणशङ्कु उत्पन्न होते हैं, और दक्षिण गोल में कोणशङ्कु का अभाव होता है, सिद्धान्तशेखर में ‘अष्टाकृत्याविहीनं त्रिगुणकृतिरसं’ इत्यादि संस्कृतोपपत्ति में लिखित श्लोकों से श्रीपति के कोणशङ्कुसाधन भाचार्योक्त के अनुसृत ही हैं, सुबंशिद्धान्त में श्री ‘त्रिज्यावर्गधृतोऽष्टाज्यावर्गोत्तात्’ इत्यादि से यही कोणशङ्कु का ध्यानवन कहा गया है, सिद्धान्तशिरोमणि में ‘अष्टाकृति द्विगुणिता त्रिगुणस्व वर्गात्’ इत्यादि से वास्कराचार्य ने विदित अष्टा के बराबर मुख को मानकर अष्टकृत् प्रकार से कोणशङ्कु का साधन किया है अर्थात् द्विगुणित अष्टावर्ग = $२\text{यु}^2 = \text{ह्यग्या}^2$, विज्ञावर्ग में द्विगुणित अष्टावर्ग को घटाने से अष्टास्तव कोणशङ्कु वर्ग रहता है, उसका मूल लेकर अष्टकृतल साधन करना उस (अष्टकृतल) को अष्टा ने संस्कार करने से अष्टास्तव मुख होता है, इस तरह अष्टकृत् कर्म करने से वास्तव कोणशङ्कु प्राप्त होता है, लेकिन यदि मुख = अष्टा $\times ४२$

$$= \sqrt{\frac{\text{त्रि}^2}{२}} \text{ तब इस प्रकार का व्यवहार होता है जैसे, } २ \text{यु}^2 = २ \text{ अष्टा}^2 = \text{त्रि}^2 =$$

ह्यग्या^२ अतः $\sqrt{\text{त्रि}^2 - २ \text{अष्टा}^2} = ० = \text{कोणशङ्कु}$, इनसे अष्टकृतल भी = ०, इनको अष्टा में संस्कार करने से पूर्ण मुख ही होता है, इसलिये वास्कराचार्य की प्रवृत्ति ही नहीं होती,

यदि भुज > ज्या ४५ तब कोणशङ्कु का मान ऋणः आत्मक होता है, इसलिये भुज = ज्या ४५ स्वीकार कर यदि भ्रमा का मान लाते हैं तो उससे भ्रम्य भ्रमा में उत्तरगोल में भास्करोक्त प्रकार का व्यभिचार होता है, यथा भास्करोक्ति से $\sqrt{\text{त्रि}^2 - २ \text{भ्र}^2} = \text{कोणशङ्कु}$, इससे

$$\text{शङ्कुतल} = \frac{\text{पमा}}{१२} \sqrt{\text{त्रि}^2 - २ \text{भ्र}^2} \text{ इससे भुज} = \frac{\text{पमा}}{१२} \sqrt{\text{त्रि}^2 - २ \text{भ्र}^2 - \text{भ्र}^2} = \text{ज्या ४५}^*$$

द्वेदगम आदि से,

$$\text{पमा} \sqrt{\text{त्रि}^2 - २ \text{भ्र}^2} = १२ \cdot \text{ज्या ४५} + \text{भ्र} \cdot १२ = १२ (\text{भ्र} + \text{ज्या ४५}) \text{ वर्ग करने से}$$

$$\text{पमा}^2 \cdot \text{त्रि}^2 - \text{पमा}^2 \cdot २ \text{भ्र}^2 = १४४ (\text{भ्र}^2 + २ \text{भ्र} \cdot \text{ज्या ४५} + \text{ज्या}^2 ४५) \text{ दोनों पक्षों को दो से भाग देने से}$$

$$\text{पमा}^2 \cdot \frac{\text{त्रि}^2}{२} - \text{पमा}^2 \cdot \text{भ्र}^2 = ७२ \text{भ्र}^2 + १२^2 \cdot \text{भ्र} \cdot \text{ज्या ४५} + ७२ \cdot \text{ज्या}^2 ४५ = \text{पमा}^2 \cdot \text{ज्या}^2 ४५ \\ - \text{पमा}^2 \cdot \text{भ्र}^2 \text{ समशोधन करने से}$$

$$\text{पमा}^2 \cdot \text{ज्या}^2 ४५ - ७२ \cdot \text{ज्या}^2 ४५ = \text{पमा}^2 \cdot \text{भ्र}^2 + १२^2 \cdot \text{भ्र} \cdot \text{ज्या ४५} + ७२ \cdot \text{भ्र}^2 \text{ तुल्यगुणक को अलग करने से}$$

$$\text{ज्या}^2 ४५ (\text{पमा}^2 - ७२) = \text{भ्र}^2 (\text{पमा}^2 + ७२) + १२^2 \cdot \text{भ्र} \cdot \text{ज्या ४५}$$

$$\therefore \frac{\text{ज्या}^2 ४५ (\text{पमा}^2 - ७२)}{\text{पमा}^2 + ७२} = \text{भ्र}^2 + \frac{१२^2 \cdot \text{भ्र} \cdot \text{ज्या ४५}}{\text{पमा}^2 + ७२} \text{ वर्ग पूरा करने से}$$

$$\frac{\text{ज्या}^2 ४५ (\text{पमा}^2 - ७२)}{\text{पमा}^2 + ७२} + \left(\frac{७२ \cdot \text{ज्या ४५}}{\text{पमा}^2 + ७२} \right)^2 = \text{भ्र}^2 + \frac{१२^2 \cdot \text{भ्र} \cdot \text{ज्या ४५}}{\text{पमा}^2 + ७२} + \left(\frac{७२ \cdot \text{ज्या ४५}}{\text{पमा}^2 + ७२} \right)^2$$

$$\text{प्रथम पक्ष में समच्छेदादि करने से} \frac{\text{ज्या}^2 ४५ \cdot \text{पमा}^2}{(\text{पमा}^2 + ७२)^2} = \text{भ्र}^2 + \frac{२ \cdot ७२ \text{भ्र} \cdot \text{ज्या ४५}}{\text{पमा}^2 + ७२}$$

$$+ \frac{(७२ \cdot \text{ज्या ४५})^2}{(\text{पमा}^2 + ७२)^2} \text{ मूल लेने से} \frac{\text{ज्या ४५} \times \text{पमा}^2}{\text{पमा}^2 + ७२} = \text{भ्र} + \frac{७२ \cdot \text{ज्या ४५}}{\text{पमा}^2 + ७२}$$

$$\therefore \text{भ्र} = \frac{\text{ज्या ४५} \cdot \text{पमा}^2}{\text{पमा}^2 + ७२} - \frac{७२ \cdot \text{ज्या ४५}}{\text{पमा}^2 + ७२} = \frac{\text{ज्या ४५} (\text{पमा}^2 - ७२)}{\text{पमा}^2 + ७२} \text{ इससे "गुणभाष्योना-}$$

अप्रभावर्धनिकी" इत्यादि संस्कृतोपपत्ति में लिखित म. म. पण्डितसुधाकरद्विवेदी का वृत्त उपपन्न हुआ ॥ दक्षिणगोल में व्यभिचार सिद्धान्तधरोमणि की टिप्पणी में 'अस-प्रवाक्यविधि' इत्यादि से संशोधन किया गया है ।

किस देश में किस दोस में बार कोणशङ्कु होते हैं उसके जिन विचार करते हैं

जिस देश में परमात्रा = ज्या'४५ उस देश की पलभा मापन करते हैं, कल्पना करते हैं

$$\text{पलभा मान} = \text{य तब पक}^2 = \text{य}^2 + १२^2 \therefore \frac{(\text{य}^2 + १२^2)}{१२^2} \text{ ज्या'जि} = \text{परमात्रा}^2 = \text{ज्या'४५}$$

$$\text{छेदगन करने से य' ज्या'जि} + १२^2 \cdot \text{ज्या'जि} = १२^2 \cdot \text{ज्या'४५ समशोधन से य' ज्या'जि} = १२^2 \cdot \text{ज्या'४५} - १२^2 \cdot \text{ज्या'जि} = १२^2 (\text{ज्या'४५} - \text{ज्या'जि}) \therefore \text{य} = १२^2 \frac{(\text{ज्या'४५} - \text{ज्या'जि})}{\text{ज्या'जि}}$$

$$\text{मूललेने से य} = \frac{१२\sqrt{\text{ज्या'४५} - \text{ज्या'जि}}}{\text{ज्या'जि}} = १७।५।२२ \text{ इससे सिद्ध हुआ कि जिस देश में}$$

पलभा = १७।५।२२ होगी उस देश में परमात्रा = ज्या'४५ होगी, १७।५।२२ इससे अधिक पलभा जिस देश में होगी उस देश में दक्षिणगोल में कोणशङ्कु का प्रभाव होगा। क्योंकि वहाँ २ घमा > जि', उत्तरगोल में कोणशङ्कु चतुष्टय (चार कोणशङ्कु) उत्पन्न होते हैं, इससे भास्करोक्त भाष्य उपपन्न होता है इति ॥५४-५५-५६॥

इदानीं भुजद्वयज्ञानात्पलभाज्ञानमाह

प्राच्यपराशङ्कुतलान्तरद्वयव्यस्तकर्णवधविवरम् ।

समदिशि विषुवच्छायाव्यतिरेक्यं कर्णविवरद्वयम् ॥५७॥

सु. भा.—प्राच्यपराशङ्कुतलान्तरं शङ्कुमूलप्राच्यपरान्तरम् । अर्थात् द्वादशाङ्गुलशङ्कोर्भुजः । एवं भुजद्वयस्य व्यस्तकर्णवधस्य समदिशि विवरमन्य-दिश्येक्यं कर्णयोर्विवरेण हृतं विषुवच्छाया भवति ।

छायाकर्णगोले शङ्कुतलं पलभातुल्यं भवति कथमिति प्रदर्शयते,

$$\frac{\text{पभा. इशं}}{१२} = \text{शङ्कुतलम्} \therefore \frac{१२. त्रि}{१२. छाक} = \text{इशं अत उत्त्वापनेन} \frac{\text{पभा. १२. त्रि}}{१२. छाक} = \text{शङ्कु-}$$

$$\text{तलम्} । \text{छायाकर्णगोले शङ्कुतलम्} = \frac{\text{पभा. १२. त्रि. छाक}}{१२. छाक. त्रि} = \text{पभा. शङ्कुतलाप्रासंस्का-}$$

रेण भुजो भवति, छायाकर्णवृत्ताग्रा यथा दिक्का, उत्तरगोले रवेः समप्रवेशात् पूर्वं
छायावृत्ताग्रा शङ्कुतलतुल्यया पलभया हीना तदोत्तरभुजो भवेदत उत्तरेण भुजेन
हीना छायावृत्ताग्रा पलभा भवेत् । समप्रवेशादुपरि पलभायां छायावृत्ताग्रा
शुद्धा भवति, ततोऽवशिष्टं दक्षिणे भुजोऽस्त्येन युताग्रा पलभा भवति, दक्षिणगोले
सर्वदेव छायाकर्णवृत्ताग्रा पलभयोर्गतेन भुजो भवत्यतश्छायाकर्णवृत्ताग्रया हीनं भुज-
मानं पलभा भवेदिति सिद्धान्तश्चेकरे "यथाच्छायावलयविहिता संव सौम्यान्तरेण

हीना युक्ता नियतमनुना दक्षिणेनाक्षभा स्यात्, । एवं मेघप्रभृतिषु गते भास्करे मेघ-
षट्सु जूकादिस्थे द्युतिमति तयैवान्तरं वर्जितं स्यात्” श्रीपत्युक्तमिदमाचार्योक्तश्लो-
कान्तरमात्रमेवेति ॥५८॥

अब प्रकारान्तर से पलभा ज्ञान को कहते हैं

हि. भा.—जेषादि छः राशिओं में अर्थात् उत्तर गोल में उत्तर अन्तर अर्थात् द्वादशा-
ङ्गुल शङ्कु मूच और पूर्वापर रेखा के अन्तर (भुज) को छायावर्णवृत्ताग्रा में घटाने से तथा
दक्षिण अन्तर (दक्षिण भुज) को जोड़ने से पलभा होनी है, तुलादि छः राशियों में अर्थात्
दक्षिण गोल में उस अन्तर (भुजमान) में छायाकर्णवृत्ताग्रा को हीन करने से पलभा
होती है इति ॥५८॥

उपपत्ति

छायावर्णगोल में शङ्कुतल, पलभा के बराबर होता है जैसा, $\frac{\text{पभा. इशं}}{१२} = \text{शङ्कु-}$

तल, $\therefore \frac{\text{त्रि. १२}}{\text{छाक}} = \text{इशं अतः उत्पापन देने से } \frac{\text{पभा. त्रि. १२}}{१२. \text{छाक}} = \text{शङ्कुतल, इसको छाया-}$

कर्ण गोल में परिणामन करने से $\frac{\text{पभा. त्रि. १२. छ क}}{१२. \text{छाक. त्रि}} = \text{पभा} = \text{छायाकर्णगोलीय-}$

शङ्कुतल, उत्तरगोल में समप्रवेश से पहले छायावृत्ताग्रा में शङ्कुतल तुल्य पलभा को घटाने
से उत्तर भुज होता है इसलिये छायावृत्ताग्रा में उत्तर भुज को घटाने से पलभा होती है, सम
प्रवेश से ऊपर पलभा में छायाकर्णवृत्ताग्रा घटाने से शेष दक्षिण भुज होता है इसलिए इस-
भुज को उस अग्रा में जोड़ने से पलभा होता है, दक्षिण गोल में सदा छायाकर्णवृत्ताग्रा और
पलभा का योग करने से भुज होता है अतः भुज में छायाकर्णवृत्ताग्रा को घटाने से पलभा
होती है, सिद्धान्तशेखर में “अग्राच्छायावलयविहिता सैव सीमान्तरेण” इत्यादि संस्कृतो-
पपत्ति में लिखित श्रीपति-प्रकार आचार्योक्त के अनुरूप ही है इति ॥५८॥

इदानीं मिष्टच्छायावृत्ते पलभाग्रयो संस्थानमाह

इष्टच्छायावृत्ते तदग्रयोर्यदुदयास्तमयसूत्रम् ।

अत्रोपपत्तिः । उत्तरगोले पूर्वविधिना याम्यो भुजः = वि - कम्प्रा = भु । अतः कर्णवृत्ताग्रा = वि - भु । दक्षिणगोले सर्वदा याम्यो भुजः = वि + कम्प्रा = भु । अतः कर्णवृत्ताग्रा = भु - वि । एवं याम्ये भुजे भुजपलभयोरन्तरं कर्णवृत्ताग्रा फलिता । उत्तरगोले सौम्यो भुजः = कम्प्रा - वि = भु । अतः कम्प्रा = वि + भु । एवं कर्णवृत्ताग्रानयनमुपपन्नम् । कर्णवृत्ताग्रा त्रिज्यागुणा छायाकर्णहृता जाताऽग्रा = $\frac{\text{कम्प्रा} \cdot \text{त्रि}}{\text{छाक}}$ । इयं लम्बज्यागुणा त्रिज्याभक्ताऽक्षक्षेत्रसाजात्याज्जाता क्रान्ति-

ज्या = $\frac{\text{लंज्या} \cdot \text{कम्प्रा}}{\text{छाक}}$ । अत उपपद्यते क्रान्तिज्यानयनम् ॥६०॥

वि. भा. — शङ्कुप्राच्यपरान्तरं (लघुद्वादशाङ्गुलसम्बन्धी भुजः) विषु-
वच्छाया (पलभा), याम्ये (दक्षिणभुजे) ऽनयोरङ्गुलान्तरं, उदक् (उत्तरभुजे)
अनयोरैक्यं यत्तल्लम्बगुणं (लम्बज्यागुणितं), छायाकर्णभक्तं तदा क्रान्तिः
(क्रान्तिज्या) भवेदिति ॥६०॥

अत्रोपपत्तिः

उत्तरगोले (५८ श्लोकोक्त्या) दक्षिणभुजः = पभा - कर्णवृत्ताग्रा = भु अतः
कर्णवृत्ताग्रा = पलभा - भु । एतेन दक्षिणो भुजे भुजपलभयोरन्तरं कर्णवृत्ताग्रा
निष्पन्ना, उत्तरगोले उत्तरभुजः = कर्णवृत्ताग्रा - पलभा, = भु, अतः कर्णवृत्ताग्रा =
पलभा + भु, ततोऽनुपातेना 'यदि छायाकर्णेन कर्णवृत्ताग्रा लभ्यते तदा त्रिज्याया
किमिति' ज्ञेनाग्रा = $\frac{\text{कर्णवृत्ताग्रा} \cdot \text{त्रि}}{\text{छाक}}$ ततो यदि त्रिज्याया लम्बज्या लभ्यते तदाऽग्रा

वि. मित्यनुपातेन क्रान्तिज्या = $\frac{\text{लंज्या} \cdot \text{अग्रा}}{\text{त्रि}} = \frac{\text{लंज्या} \cdot \text{कर्णवृत्ताग्रा} \cdot \text{त्रि}}{\text{छाक} \cdot \text{त्रि}}$

= $\frac{\text{लंज्या} \cdot \text{कर्णवृत्ताग्रा}}{\text{छाक}}$ एतेनाऽऽचार्योक्तमुपपन्नम् । सिद्धान्तशेखरे "स्नानरान्तरपल-

प्रभयोर्मवेद्यत् याम्येऽन्तरं युतिरुदक्च्युतिवृत्तजाऽग्रा । लम्बाहता भवति कर्णहृताऽ
पमज्योति" श्रीपत्युक्तमिदमाचार्योक्तानुरूपमेव, सूर्यसिद्धान्तेऽपि "दृष्टाग्राधनी तु
लम्बज्या स्वकर्णङ्गुलभाजितेत्यादि" ब्रह्मगुप्तो (भाचार्य) क्तसदृशमेवेति ॥६०॥

अत्र भुज और छाया से क्रान्तिज्यानयन को कहते हैं

हि. भा. — दक्षिणभुज में पलभा और लघुद्वादशाङ्गुल सम्बन्धी भुज के अन्तर को

और उत्तर भुज में इन दोनों के योग की सम्बन्धता ने गुणाकर छायाएँ में भाग देने से क्रान्तिज्या होती है इति ॥६०॥

उपपत्ति

उत्तर गोल में (१= श्लोकोक्त ने) दक्षिणभुज=पश्चा—कर्णवृत्ताप्रा=भू, अतः कर्णवृत्ताप्रा=पश्चा—भू इससे दक्षिण भुज में भुज और पश्चा का अन्तर कर्णवृत्ताप्रा निश्च हई, उत्तरगोल में उत्तरभुज=कर्णवृत्ताप्रा—पश्चा=भू अतः कर्णवृत्ताप्रा=पश्चा+भू, अब अनुपात करने हैं यदि छायाएँ में कर्णवृत्ताप्रा पाते हैं तो त्रिज्या = क्या इससे पश्चा आती है $\frac{\text{कर्णवृत्ताप्रा.त्रि}}{\text{छाक}} = \text{पश्चा}$, इससे अनुपात करते हैं यदि त्रिज्या में सम्बन्धता

पाते हैं तो पश्चा में क्या, इससे क्रान्तिज्या आती है, $\frac{\text{त्रिज्या.पश्चा}}{\text{त्रि}} = \frac{\text{त्रिज्या.कर्णवृत्ताप्रा.त्रि}}{\text{छाक.त्रि}} =$

$\frac{\text{त्रिज्या. कर्णवृत्ताप्रा}}{\text{छाक}} = \text{क्रांज्या}$ इससे आचार्योंक उपपन्न हुआ, सिद्धान्तशेखर में “रेखानरान्तर-

पलप्रमयोः” इत्यादि संस्कृतोपपत्ति में लिखित श्लोक से श्रीपति आचार्योंकानुरूप ही कहते हैं. सूर्यसिद्धान्त में भी “दृष्टाध्याघ्नी तु सम्बन्ध्या स्वकर्णाङ्गुलमाजिता” इत्यादि आचार्योंक-सहस्य ही है इति ॥६०॥

अब क्रांतिज्या से रवि के घानयन को कहते हैं

हि. भा.—क्रांतिज्या को त्रिज्या से गुणा कर जिनज्या से भाग देने से रवि भुजज्या
होती है, उसका चाप मेषादि तीन राशियों (प्रथमपद) में स्फुट रवि होता है, कर्कशादि तीन
राशियों (द्वितीय पद) में उस चाप को छः राशियों में घटाने से तुलादि तीन राशियों
(तृतीय पद) में चाप में छः राशि जोड़ने से, मकरादि तीन राशियों (चतुर्थ पद) में चाप
को बारह राशि में घटाने से स्फुट रवि होता है, शेष की व्याख्या स्पष्ट है इति ॥६१-६२॥

उपपत्ति

यदि जिनज्या से त्रिज्या पाते हैं तो रवि की क्रांतिज्या में क्या इस क्रांतिज्या के
अनुपात से रविभुजज्या आती है,

त्रि.क्रांज्या
त्रिज्या = रविभुजज्या, इसका चाप प्रथम पद में स्फुट रवि होता है । द्वितीय पद में

उस चाप को छः राशि में घटाने से तृतीय पद में चाप में छः राशि जोड़ने से, चतुर्थ पद
में चाप को बारह राशि में घटाने से स्फुट रवि होता है । यह गोल में प्रत्यक्ष देखा जाता
है, सिद्धान्तशिरोमणि में “अद्विज्याग्रं चरते चरत्तयः प्रजायतेऽन्वेयुः” इत्यादि से भास्करा-
चार्य व्याख्याति के अनुकर ही कहते हैं, लेकिन भास्करादि व्याख्याओं ने रवि का पदज्ञान
अनुवर्तन द्वारा किया है जो ठीक नहीं है इसके लिये सिद्धान्ततत्त्वविवेक में कमलाकर ने
“अनुचिन्तैरिदं पूर्वैः” इत्यादि संस्कृतोपपत्ति में लिखित श्लोक से उसका निराकरण
किया है । तथा उसके वास्तव ज्ञान के लिये अपना प्रकार “आद्ये पदेऽपचयिनी पलभाषिका
स्यात्” इत्यादि दिखसाया है । इसकी युक्ति इस प्रकार है—विषुवद् दिग् में व्यापकाला
में हाइड्रानुल चक्र की जो छाया होती है वह पचमा है, उस दिग् से केकर प्रत्येक दिन
निरक्ष देश से उत्तर देश में $\frac{\text{नतांशज्या. १२}}{\text{क्रांतिज्या}} = \frac{\text{इज्या. १२}}{\text{चक्रज्या}}$ = $\frac{\text{इज्या. १२}}{\text{चक्रज्या}}$ = $\frac{\text{इज्या. १२}}{\text{चक्रज्या}}$ को

देखने से मध्यनतांश के अपचय (ह्रास) से मध्यशङ्कु के उपचय (वृद्धि) से मध्यच्छाया का उत्तरोत्तर अपचय होता है इसलिए पलभा से अल्प मध्यच्छाया का उत्तरोत्तर अपचय होने से रवि का प्रथम पद होता ही है, द्वितीय पद में मध्यनतांश उत्तरोत्तर बढ़ता है जबतक तुलादि सम्पत्ता में रवि जाता है, इसलिये पलभा से अल्प उत्तरोत्तर वृद्धिमती मध्यच्छाया होने से द्वितीय पद होता है, तृतीय पद में मध्यच्छाया पलभा से अधिक उत्तरोत्तर उपचित होती है (रवि के दक्षिण गमन के कारण से), चतुर्थ पद में पुनः उत्तरगमन प्रवृत्तिसे उत्तरोत्तर नतांश का अपचय होता है इसलिए पलभा से अधिक छाया अपचयमती होती है, अतः “आद्ये पदेऽपचयिनी” इत्यादि युक्तियुक्त कहा गया है। निरक्ष देश से दक्षिण देश में प्रथम पद में मध्यनतांश के उपचय से मध्यच्छाया का उपचय होता है लेकिन वहाँ स्वस्वस्तिक से उत्तर में रवि के रहने के कारण छायाग्र दक्षिण दिशा ही में होता है इसलिये “वृद्धिं प्रयान्ती यदि दक्षिणाग्रा” इत्यादि संस्कृतोपपत्ति में लिखित पद्य युक्तियुक्त कहा गया है, द्वितीय पद में रवि के उत्तरोत्तर दक्षिण गमन के कारण मध्यनतांश के अपचय से मध्यच्छाया का अपचय होता है, तृतीय पद में और चतुर्थ पद में नतांश के उपचय और अपचय के अनियम से वहाँ मध्यच्छाया द्वारा एक नियम से पदज्ञान नहीं होता है, ये सब बातें गोल को देखने से स्पष्ट हैं, सिद्धान्तशेखर में “आद्ये पदेऽपचयिनी” इत्यादि चमत्कृतियुक्त प्रकार देखा जाता है। इस से सिद्ध होता है कि यह रवि का पदज्ञान-प्रकार वस्तुनः श्रौपित ही का है, कमलाकर का नहीं है इति ॥६१-६२॥

इदानीं चन्द्रशृङ्गोन्नतौ रविशङ्कुवर्थं विशेषमाह

शशिशृङ्गोन्नत्यर्थं रात्रेर्गतशेषनाडिका शङ्कुः ।

विपरीतगोलविधिना रात्र्यर्धकान्तिराभिर्वा ॥६३॥

हि. भा.—ग्रच्छे गणक लोग प्रायः पर्वज्ञान के लिये समयज्ञान को कहते हैं अर्थात्
ग्रमावास्था—पूर्णिमा आदि पर्वों के आरम्भ और अन्त समय प्रधान रूप से वेदोक्त कर्मा-
नुष्ठान के लिए सद्गणकों वा वेदज्ञों को प्रयोजनीभूत होते हैं अतएव ज्योतिःशास्त्र में भी
मुख्य रूप से उन पर्वों का किस समय में आरम्भ होता है और किस समय में अन्त होता है
इसी का ज्ञान किया जाता है, चन्द्रग्रहण और सूर्यग्रहण के ज्ञान के लिये जो वास्तव भेद
(दिग् देशकालादि) हैं वे निम्नलिखित भेदों से स्फुट होते हैं, दिग्भेद (चन्द्रग्रहण में पूर्व-
दिशा में प्रग्रहण होता है और सूर्यग्रहण में पश्चिम में होता है) वर्णभेद (चन्द्रग्रहण में
अर्धग्रास-अर्धाधिकग्रास-सर्वग्रासादिषु चन्द्र के वर्ण कृष्ण-कृष्णारक्त-कपिलवर्ण आदि होते
हैं सूर्य ग्रहण में सूर्य का वर्ण सदा कृष्ण ही होता है) बलनभेद (चन्द्रग्रहण में स्पाशिक
मौक्षिक बलन पूर्व और पश्चिम से सूर्यग्रहण में पश्चिम और पूर्व) वेला
(समय) भेद (चन्द्रग्रहण में अन्त तिथ्यन्त ही में प्रग्रह होता है, सूर्यग्रहण में वह निरम

नहीं है। निमीलन भेद और उन्मीलनभेद (वे चन्द्रग्रहण में और सूर्यग्रहण में परस्पर विपरीत होते हैं) स्थिति भेद (चन्द्रग्रहण में स्थिति महती होती है और सूर्यग्रहण में नष्ट) विमर्दकाल (चन्द्रग्रहण में मर्याद और सूर्यग्रहण में अस्तर) स्पर्श (स्पर्शकालनिर्णय) भेद (चन्द्रग्रहण में स्थित्यर्थ में और सूर्यग्रहण में सम्बन्ध संस्कृतस्थित्यर्थ में) छायाभेद (ग्रह-प्रपन्न शङ्कुभेद से प्रपहादियों में होते ही हैं) मोक्षभेद (चन्द्रग्रहण में पश्चिम में और सूर्यग्रहण में पूर्व में मोक्ष होता है) ग्रामभेद (चन्द्रग्रहण में घर में और सूर्यग्रहण में नतिमंस्कृतशर में) दृष्टग्रामभेद (चन्द्रग्रहण में तात्कालिकशर में और गणिताग्राम स्थित्यर्थ में भी, सूर्यग्रहण में नतिमंस्कृतशर में और स्फुटस्थित्यर्थ में भी) परिवर्तन भेद (चन्द्रग्रहण में गणिताग्रामशर में और सूर्यग्रहण में नतिमंस्कृतशर में) इन तरह यहां चौदह भेद होते हैं, जिस कारण से चन्द्रग्रहण और सूर्यग्रहण के ज्ञान से उन चौदह भेदों का ज्ञान होता है। इस हेतु से मैं चन्द्रग्रहण और सूर्यग्रहण को कहता हूं इति ॥१-२-३॥

इदानीं तात्कालिकीकरणमाह

तिथिगतगम्ये भुक्तिगुणे भुक्त्यन्तरहृते फलेनयुतो ।

रविशशिनी समलिप्ती पातस्तात्कालिको भवति ॥४॥

सु. भा.—तिथिगतगम्ये तिथिगतगम्यकले भुक्तिगुणे रविभुक्त्या चन्द्रभुक्त्या च गुणे । उभयत्र रविचन्द्रभुक्त्यन्तरेण हृते । गतवासने फलेनो गम्ये फलयुतो रविशशिनी । एवं तौ तात्कालिकौ तिथ्यन्ते समलिप्ता भवतः । एवं पातगत्या पातोऽप तात्कालिको भवति ।

अत्रोपपत्तिः । तिथिगतगम्ये कले षष्टिगुणौ रविचन्द्रगत्यन्तरभक्त गतेष्या घटिकास्ता गतिगुणाः षष्टिहृताश्चालनकलाः स्युः । एवमत्र षष्टितुल्ययोर्गुणहरयो-
नशिशाद्योक्ता क्रियोत्पद्यते ॥४॥

वि. भा.—तिथिगतगम्ये (तिथिगतगम्यकले) भुक्तिगुणे (चन्द्रग्रहणा रविग्रहणा च गुणिते) भुक्त्यन्तरहृते (रविचन्द्रयोर्भुक्त्यन्तरेण भक्ते) गतवासने फलेन होनी, गम्यचालने फलेन युतो चन्द्ररवी, तिथ्यन्ते तात्कालिकौ समलिप्ता चन्द्ररवी भवतः । एवं स्वगत्या पातोऽप तात्कालिको भवतीति ॥४॥

अत्रोपपत्तिः

यदिरविचन्द्रगत्यन्तरकलायां षष्टिघटिका सम्बन्धे तदा तिथिगतकलायां गम्यकलायां च किमित्यनुपातेन तिथिगतकलायां गम्यकलायां समान्यन्ति, ततः षष्टिघटिकायां स्वस्वमतिकला सम्बन्धे तदा तिथिगतकलायां तिथिगतगम्यकलायां

$$\text{च किमिति जातः चालनकला चन्द्रस्य} = \frac{६० \times \text{तिथिगतक}}{\text{रविचन्द्रगत्यन्तरक}} \times \frac{\text{चंगकला}}{६०} =$$

$$\frac{\text{तिथिगतक} \times \text{चंगकला}}{\text{रविचन्द्रगत्यन्तरक}}, \text{ एवं गम्यचन्द्रचालनकला} = \frac{६० \times \text{तिथिगम्यक}}{\text{रविचन्द्रगत्यन्तरक}} \times \frac{\text{चंगकला}}{६०}$$

$$= \frac{\text{तिथिगम्यक} \times \text{चंगक}}{\text{रविचन्द्रगत्यन्तरक}}, \text{ एवमेव रवेर्गतचालन कला} = \frac{६० \times \text{तिथिगतक}}{\text{रविचन्द्रगत्यन्तरक}} \times$$

$$\frac{\text{रविगतक}}{६०} = \frac{\text{तिथिगतक} \times \text{रविगतक}}{\text{रविचन्द्रगत्यन्तरक}},$$

$$\text{रवेर्गम्यचालनकला} : = \frac{६० \times \text{तिथिगम्यक}}{\text{रविचन्द्रगत्यन्तरक}} \times \frac{\text{रविगतक}}{६०} = \frac{\text{तिथिगम्यक} \times \text{रविगतक}}{\text{रविचन्द्रगत्यन्तरक}}.$$

एतेनाऽऽचार्योक्तमुपपन्नमिति ॥४॥

अब तात्कालिकीकरण को कहते हैं

हि. भा.—तिथिगत कला को और तिथिगम्यकला को चन्द्रगति और रविगति से पृथक् गुणाकर रवि और चन्द्र के गत्यन्तर से भाग देने से जो फल हो गतचालन में उन फलों को चन्द्र और रवि में हीन करना और गम्यचालन में युत करना तब तिथ्यन्त में तात्कालिक चन्द्र और रवि समलिप्तिक (समान कलात्मक) होते हैं, इस तरह अपनी गति से पात (चन्द्रपात) भी तात्कालिक होता है इति ॥४॥

उपपत्ति

यदि रवि और चन्द्र की गत्यन्तर कला में साठ घटी पाते हैं तो तिथिगतकला और तिथिगम्यकला में क्या इस अनुपात से तिथिगतघटी और तिथिगम्यघटी आयी

$$\text{है, } \frac{६० \times \text{तिथिगतक}}{\text{रविचन्द्रगत्यन्तरक}} = \text{तिथिगतघटी}, \frac{६० \times \text{तिथिगम्यक}}{\text{रविचन्द्रगत्यन्तरक}} = \text{तिथिगम्यघटी पुनः अनुपात}$$

करते हैं, यदि साठ घटी में अपनी-अपनी गतिकला पाते हैं तो तिथिगत घटी में और तिथि

$$\text{गम्य घटी में क्या इस अनुपात से चन्द्र की गतचाल कला} = \frac{६० \times \text{तिथिगतक}}{\text{रविचन्द्रगत्यन्तरक}}$$

$$\times \frac{\text{चंगक}}{६०} = \frac{\text{तिथिगतक} \times \text{चंगक}}{\text{रविचन्द्रगत्यन्तरक}}$$

$$\text{अब चन्द्रगम्यचालन कला} = \frac{६० \times \text{तिथिगम्यक}}{\text{रविचन्द्रगत्यन्तरक}} \times \frac{\text{चंगक}}{६०} = \frac{\text{तिथिगम्यक} \times \text{चंगक}}{\text{रविचन्द्रगत्यन्तरक}}, \text{ इसी तरह}$$

रवि की गतचालन कला = $\frac{६० \times \text{नियिगत कला}}{\text{रविचन्द्रगत्यन्तरक}} \times \frac{\text{रविगक}}{६०} = \frac{\text{नियिगतक} \times \text{रविगक}}{\text{रविचन्द्रगत्यन्तरक}}$, रवि

की गम्यचालन कला = $\frac{६० \times \text{नियिगम्यक}}{\text{रविचन्द्रगत्यन्तरक}} \times \frac{\text{रविगक}}{६०} = \frac{\text{नियिगम्यक} \times \text{रविगक}}{\text{रविचन्द्रगत्यन्तरक}}$, इसमें

प्राचार्योक्त उपासनं दृष्ट्वा ॥५॥

इदानीं तिथ्यन्ते शरकलानयनमाह

पद्यमुपपन्नं भवतीति ॥ ५ ॥

अथ तिथ्यन्त में चन्द्रगरकलानयन को कहते हैं ।

हि. भा.—सपात तात्कालिक चन्द्रभुज्या को दो सौ मन्तर २७० में गुणा कर
त्रिज्या से भाग देने से फल चन्द्रगर कला होती है, सपात चन्द्र के छः राशि में कम रहने में
उम (गरकला) की दिशा उत्तर होती है, तथा छः राशि से अधिक रहने में गरकला की
दिशा दक्षिण होती है इति ॥ ५ ॥

उपपत्ति ।

क्रान्तिवृत्त और विमण्डल के सम्पात पात संज्ञक है, पात स्थान में नवत्यंश व्यासांश
वृत्त उन दोनों (क्रान्तिवृत्त और विमण्डल) वृत्तों के परमान्तर वृत्त है, क्रान्तिवृत्त और
विमण्डल के अन्तर्गत परमान्तर वृत्तीय चाप परमशर है, विमण्डल में जहाँ चन्द्रबिम्ब केन्द्र है
उसके ऊपर कदम्ब प्रोत वृत्त करने से क्रान्तिवृत्त में जहाँ लगता है वह चन्द्र स्थान है,
चन्द्रबिम्ब केन्द्र से चन्द्र स्थान तक कदम्बप्रोतवृत्त में चन्द्र के मध्यमशर है, पात स्थान से
चन्द्रबिम्ब केन्द्र तक चन्द्र के विमण्डलीय भुजांश कर्ण, पातस्थान से चन्द्रस्थान तक सपात
चन्द्रभुजांश कोटि, चन्द्र मध्यमशर भुज इन तीनों भुजों से उत्पन्न एक चापीय जात्य त्रिभुज
तथा पातस्थान से परमान्तर वृत्त और विमण्डल के सम्पात पर्यन्त विमण्डल में नवत्यंश,
पातस्थान ही से परमान्तरवृत्त और क्रान्तिवृत्त के सम्पात पर्यन्त क्रान्तिवृत्त में नवत्यंश,
परमान्तर वृत्त में चन्द्र परमशर, इन तीनों भुजों से उत्पन्न द्वितीय चापीय जात्य त्रिभुज,
इन दोनों चापीय जात्य त्रिभुजों के ज्याक्षेप जातीय है इसलिये अनुपात करते हैं यदि त्रिज्या
में चन्द्र परमशरज्या पाते हैं तो विमण्डलीय चन्द्र भुजज्या में क्या इस अनुपात से चन्द्र-
मध्यम शरज्या आती है चन्द्रपरमशरज्या. चन्द्रविमण्डलीय भुज्या
त्रि

परन्तु यहाँ चन्द्र विमण्डलीय भुजांश विदित नहीं है, गणितान्त सपात चन्द्रभुजांश विदित है
इसलिए आचार्य ने चन्द्र विमण्डलीय भुजांश तुल्य ही सपात चन्द्र भुजांश को स्वीकार
किया है तब चन्द्रपरमशरज्या. सपातचन्द्रभुज्या
त्रि

अनेकत्व की स्वीकार किया है तब चन्द्रपरमशर × सपात चन्द्रभुज्या
त्रि

२७० × सपात चन्द्रभुज्या त्रि. वह शर सपात चन्द्र मोल विद्या का होता है अर्थात् सपात चन्द्र

जिस मोल में रहते हैं उसी मोल का होता है इससे आचार्यों ने उत्पन्न हुआ, परन्तु वह धामन
ठीक नहीं है क्योंकि विमण्डलीय चन्द्र भुजांश कर्ण चाप है और सपात चन्द्रभुजांश कोटि चाप

है इन दोनों का आचार्य ने तुल्य मान लिया है तथा चंपरमशरज्या = चंपरमशर, एवं चमध्य-
शरज्या = चमध्यमशर स्वीकार किया है, जो कि अनुचित है, अतः वास्तवानयन करते हैं। चन्द्र
विमण्डलीय भुजांश, सपात चन्द्रभुजांश, और चन्द्रमध्यमशर इन तीनों अवयवों से उत्पन्न चापीय
जात्य त्रिभुज में चन्द्र विमण्डलीय भुजांश और सपात चन्द्र भुजांश से उत्पन्न कोण = चंप-
रमशर, तब उक्त त्रिभुज में 'मध्यजा दोर्ज्या त्रिज्या गुणा प्रान्त्यस्पर्श रेखा हतिर्मेव' इससे
तथा 'तत्कोटिमेव गृह्णीयात् स्थाने श्रवणकोणयोः' इससे भी चंपरमशरकोज्या. त्रि =
स्पचंविमण्डलीय भुकोज्या. स्पसपातचं भुज्या अतः $\frac{\text{चंपरमशरकोज्या. त्रि}}{\text{स्पसपात चभुज्या}}$ = स्पचंविमण्ड-

लीय भुकोज्या, स्पर्शरेखा खण्डों से इसका चाप कर के नवत्यंश में से घटाने से चन्द्र विमण्डलीय
भुजांश का ज्ञान हो जायगा, तब पूर्व कथित चापीय जात्य त्रिभुज में भुजकोटिज्या और कोटि
कोटिज्या का घात त्रिज्या और कर्ण कोटिज्या के घात के बराबर होता है इस नियम से
त्रि. चंविमण्डलीय भुकोज्या = चंशर कोज्या सपात चं भुकोज्या ∴
त्रि. चंविमण्डलीय भुकोज्या = चंशर कोज्या, इसके चाप को नवत्यंश में से घटाने से चन्द्रमध्य-

मशर होता है, सिद्धान्तशिरोमणि में भास्कराचार्य ने "सपाततात्कालिकचन्द्रदोर्ज्या" इत्यादि
संस्कृतोपपत्ति में लिखित श्लोक से आचार्योक्त के अनुरूप ही कहा है, सिद्धान्त शेखर में
श्रीपति "पातोनितस्य समलिप्तशीतरश्मेः" इत्यादि संस्कृतोपपत्ति में लिखित पद्य से चन्द्र
का शरानयन किया है यह भी आचार्योक्त के अनुरूप ही है केवल श्रीपति ने पात के चक्र
(बारहराशि) में शुद्ध होने के कारण सपात चन्द्र भुज्या स्थान में विपातचन्द्रभुज्या ग्रहण
किया है, और विपात चन्द्र भुज्या के गुणक चन्द्रपरमशर २७० को तथा श्रीपत्युक्त त्रिज्या
= ३४१५ हर को पांच से अपवर्तन कर देने से श्रीपति का पद्य उपपन्न होता है इति ॥ ५ ॥

शरस्य वर्गेण विवर्जिताभ्याम्। मूले खपट् ६० संगुणिते विभक्ते भुक्त्यन्तरेण
स्थितिमर्दखण्डे" भास्कराचार्यस्यायं श्लोकश्चाऽऽचार्योक्तानुरूप एवेति ॥ ७ ॥

अब ग्रासानयन को कहते हैं।

हि. भा.—ग्राह्य बिम्ब और ग्राहक बिम्ब के योगार्ध (मानैक्यार्ध) और अन्तरार्ध
के वर्गों में से शर वर्ग को घटाकर मूल लेना तब उन दोनों को साठ से गुणा कर रवि और
चन्द्र के गत्यन्तर से भाग देने से स्थित्यर्ध और विमदर्ध होते हैं इति ॥ ७ ॥

उपपत्ति

यहां संस्कृतोपपत्ति में लिखित (क) क्षेत्र को देखिये। भूभाबिम्ब और चन्द्र बिम्ब
के बहिः स्पर्श काल में चन्द्र केन्द्रोपरिगत कदम्बप्रोतवृत्त और क्रान्तिवृत्त के सम्पात से भूभा-
केन्द्र पर्यन्त क्रान्तिवृत्त में स्थित्यर्ध कला है, चन्द्र केन्द्रोपरि गत कदम्ब प्रोत वृत्त और क्रान्ति-
वृत्त के सम्पात से चन्द्रकेन्द्र तक कदम्बप्रोतवृत्त में स्पाशिक शर हैं। एवं भूभाबिम्ब और
चन्द्रबिम्ब के अन्तःस्पर्श (संमीलन) काल में चन्द्र केन्द्रोपरिगत कदम्बप्रोतवृत्त और
क्रान्तिवृत्त के सम्पात से भूभा बिम्ब केन्द्र पर्यन्त क्रान्ति वृत्त में विमदर्ध कला हैं, कदम्ब
प्रोत वृत्त में चन्द्रकेन्द्र से क्रान्तिवृत्त पर्यन्त अन्तःस्पर्शकालिक (संमीलनकालिक) शर हैं,
चन्द्रकेन्द्र और भूभाकेन्द्र गतवृत्त कर देना, भू=भूभा बिम्ब केन्द्र, चं=बहिःस्पर्शकालिक-
(स्पाशिक) चन्द्रकेन्द्र, चंर=स्पाशिकशर, रभू=स्थित्यर्धकला, चं=अन्तःस्पर्शकालिक
(संमीलन कालिक) चन्द्रबिम्ब केन्द्र, चंश=संमीलन कालिकशर, शभू=विमदर्धकला, न=
स्पर्श बिन्दु, भूचं=चन्द्रबिम्ब और भूभा बिम्ब के केन्द्रगत वृत्त में केन्द्रान्तर, चन=चन्द्रबिम्ब

व्यासार्धं, भूत = भूभाविम्ब व्यासार्धं, भूचं = चन्द्रविम्ब और भूभाविम्ब के मानैक्यार्धं, भूचं = चन्द्रविम्ब और भूभाविम्ब के मानान्तरार्धं, यहां आचार्य ने भूरचं त्रिभुज को तथा भूचं त्रिभुज को सरलाकार मान कर स्थित्यर्ध और विमर्दार्ध का आनयन किया है जैसे भूरच जात्य त्रिभुज में $\sqrt{\text{भूचं}^2 - \text{चर}} = \text{भूर} = \sqrt{\text{मानैक्यार्ध}^2 - \text{स्पाशिकशर}} = \text{स्थित्यर्धक}$, तब अनुपात करते हैं यदि रवि और चन्द्र की गत्यन्तरकला में साठ घटी पाते हैं तो स्थित्यर्धकला में क्या इससे स्थित्यर्ध घटी आती है, $\frac{६० \times \text{स्थित्यर्ध कला}}{\text{गत्यन्तर कला}} = \text{स्थित्यर्ध घटी}$, तथा भूचं जात्य

त्रिभुज में $\sqrt{\text{भूचं}^2 - \text{चर}} = \text{भूर} = \sqrt{\text{मानान्तरार्ध}^2 - \text{संमीलन कालिकशर}} = \text{विमर्दार्धकला}$, इससे पूर्ववत् अनुपात से विमर्दार्ध घटी = $\frac{६० \times \text{विमर्दार्ध कला}}{\text{गत्यन्तर कला}}$ लेकिन यहां स्पाशिक शर

और संमीलन कालिकशर विदित नहीं हैं, विदित है मध्यग्रहरण कालिकशर, इसलिये मध्यग्रहरण कालिकशर तुल्य ही स्पाशिक शर और संमीलन कालिकशर मानकर पूर्वोक्तरीति से स्थित्यर्ध और विमर्दार्ध का आनयन किया गया है जो ठीक नहीं हैं, सिद्धान्त शेखर में “मानार्ध-संयोगवियोगवर्गौ” इत्यादि संस्कृतोपपत्ति में लिखित श्रीपति का श्लोक तथा सिद्धान्त शिरोमणि में “मानार्धयोगान्तरयोः कृतिम्याम्” इत्यादि भास्कराचार्य का श्लोक आचार्योक्त के अनुरूप ही हैं इति ॥ ७ ॥

इदानीं स्थिति विमर्दार्धयोः स्फुटीकरणमाह ।

षष्ठ्या विभाजिता स्थिति विमर्ददलनाडिकागुणा स्वगतिः ।

आदौ रवौन्दुपातेष्वुणमसकृत् तेषु धनमन्ते ॥ ६ ॥

सु० भा०—स्पष्टार्थम् । अत्रोपपत्तिः । ‘स्थित्यर्धनाडीगुणिता स्वभुक्ति’ रित्यादिना ‘एवं विमर्दार्धफलोनयुक्ते’ त्यादिना च भास्करविधिना स्फुटा ॥ ९ ॥

वि. भा.—स्वगतिः (रविगतिः, चन्द्रगतिः, पातगतिश्च) स्थिति विमर्ददलनाडिका गुणा (स्थित्यर्धघटीभिर्विमर्दार्धघटीभिश्च पृथक् पृथक् गुणिता) षष्ठ्या ६० भक्ताऽऽदौ रविचन्द्रपातेषु ऋणम्, अन्ते तेषु धनं कार्यमर्थादाद्यस्थित्यर्धे धनमन्त्यस्थित्यर्धे ऋणं तथाऽऽद्यविमर्दार्धे धनमन्त्यविमर्दार्धे ऋणम्, एवमसकृद्द्वारं चारं पूर्वोक्त-कर्मणि कृते स्थित्यर्धविमर्दार्धे स्फुटे भवत इति ॥ ९ ॥

अत्रोपपत्तिः ।

यदि षष्ठ्यघटीभिश्चन्द्रगतिकला लभ्यन्ते तदा स्थित्यर्धघटीभिः किमि-

त्यनुपातेन स्थित्यर्धघटीसम्बन्धिनी चन्द्रगतिकला समागच्छति, पातस्याप्येवं स्थित्यर्धघटीसम्बन्धिनी गतिरानेया, आनीतफलाभ्यां क्रमेण हीनयुतौ चन्द्रपातौ पूर्वपिक्षया तौ विशिष्टौ भवतस्ततस्त्रिघन गुणाव्यासार्धभाजिता चन्द्रपातयोगज्येत्यादिना चन्द्रशरमानीय “छाद्येन युतोनस्य छादकमानस्ये” त्यादिना स्थिति-विमर्दार्धे आनेतव्ये ततः “षष्ठ्या विभाजिता स्थितिविमर्ददलनाडिका गुणा स्वगति” रित्यनेन स्थित्यर्धघटीसम्बन्धिनीं चन्द्रगतिकलां पातगतिं चानीय तद्धीनयुतौ चन्द्रपातौ कार्यौ तौ च पूर्वपिक्षया विशिष्टौ भवत एवमतकृतकर्मणा स्फुटं स्थित्यर्धं भवेत् । एवमेवाऽसकृतकर्मणा स्फुटं विमर्दार्धं भवतीति, सिद्धान्त-शेखरे श्रीपतिने “स्थिति विमर्ददलारव्यघटीहृता दिनकरेन्दु तमोमयभुक्तयः । गगनपट्क ६० हृताः प्रथमान्त्ययोः क्षयघने भवतस्त्वसकृत्ततः” त्यनेन, सिद्धान्त-शिरोमणी भास्कराचार्येण “स्थित्यर्धनाडी गुणिता स्वभुक्तिः षष्ठ्याहृता तद्रहितौ युतौ च । कृत्वेन्दु पातावसकृच्छराभ्यां स्थित्यर्धमाद्यं स्फुटमन्तिमं च ॥ एवं विमर्दार्धफलोनयुक्तसपातचन्द्रोद्भवसायकाभ्याम् । पृथक् पृथक् पूर्ववदेव सिद्धे स्फुटे स्त आद्यान्त विमर्दखण्डे” त्यनेन चाऽऽचार्योक्तानुरूपमेवोक्तमिति ॥१॥

अब स्थित्यर्ध और विमर्दार्ध के स्फुटी करण को कहते हैं ।

हि. भा.—अपनी गति (रविगति, चन्द्रगति, पातगति) को स्थित्यर्ध घटी और विमर्दार्ध घटी से पृथक् पृथक् गुणा कर साठ से भाग देने से जो फल हो उनको रवि, चन्द्र और पात में से ऋण करना, अन्त में घन करना अर्थात् आद्य स्थित्यर्ध में घन और अन्त्य स्थित्यर्ध में ऋण, तथा आद्य विमर्दार्ध में घन और अन्त्य विमर्दार्ध में ऋण करना चाहिये, इसनरह बार बार पूर्वोक्त कर्म करने से स्थित्यर्ध और विमर्दार्ध स्फुट होते हैं इति ॥ ६ ॥

उपपत्ति ।

यदि साठ घटी में चन्द्रगति कला पाते हैं तो स्थित्यर्ध घटी में क्या इस अनुपात से स्थित्यर्ध घटी सम्बन्धिनी चन्द्रगति कला आती है, पात की भी स्थित्यर्ध घटी सम्बन्धिनी गति इसी प्रकार लाना, इन लाये हुये फलों को क्रम से चन्द्र और पात में से हीन और युत करने से पूर्व की अपेक्षा विशिष्ट चन्द्र और पात होते हैं, इनसे “त्रिघनगुणा व्यासार्ध-भाजिता चन्द्रपातयोगज्या” इत्यादि से चन्द्रशर लाकर “छाद्येन युतोनस्य छादकमानस्ये” इत्यादि से स्थित्यर्ध और विमर्दार्ध लाना चाहिये, तब “षष्ठ्या विभाजिता स्थितिविमर्ददल-नाडिका गुणा स्वगतिः” इससे स्थित्यर्ध घटी सम्बन्धिनी चन्द्रगति कला और पातगति ले-आकर चन्द्र और पात में हीन और युत करने से पूर्व की अपेक्षा विशिष्ट चन्द्र और पात होते हैं इस तरह असकृतकर्म से स्फुट स्थित्यर्ध होता है, इसी तरह असकृतकर्म से स्फुट

विमर्दांशं होता है, सिद्धन्त मेव मे स्थिति विमर्दश्चकारादी दृष्टा एव दि मम्करोर-
पनि में निमित्त पक्ष में स्थिति, तथा सिद्धन्तविमर्दोपनि में स्थित्यर्थोर्गुणान्
स्वश्रुतिः पट्या हुता नद्विती युनौ च इत्यादि पक्षों में भाव्यत्वात् अतो आचार्योक्त के
अनुसृत ही कहने हैं इति ॥ ६ ॥

इदानीं निमीलनोन्मीलनकालानयनमाह ।

स्पर्शान्निमीलनं स्थितिदले विमर्दांशंहीनिते पञ्चात् ।

मोक्षादर्वागुन्मीलनं विमर्दस्तदंशार्धः ॥ १० ॥

सु० भा०—स्थितिदले स्पर्शस्थित्यर्थे विमर्दांशंहीनिते काले स्पर्शान् पञ्चात्
निमीलनं भवति । एवं मोक्षस्थित्यर्थे उन्मीलनविमर्दांशंहीनिते काले मोक्षादर्वाङ्
पूर्वमुन्मीलनं भवति । तयोर्निमीलनोन्मीलनयोः कालयोर्योगाच्च विमर्दः । अर्थाच्चो-
गार्धं कालपर्यन्तमेव छादकबिम्बे छाद्यबिम्बस्य निमज्जनं भवति ।

अत्रोपपत्तिः । स्थित्यर्थं विमर्दांशं परिभाषायाः स्फुटा ॥ १० ॥

वि. भा.—स्थितिदले (स्पर्शस्थित्यर्थे) विमर्दांशंहीनिते काले स्पर्शान्

तात्कालिकविक्षेपः कोटिस्तद्वर्गयुतिपदं कर्णः ।

मानैक्यार्धात् कर्णं विशोध्य तात्कालिको ग्रासः ॥ १२ ॥

सु० भा०—इष्टं स्पर्शिकादिकं तत् सजातीयं स्थितिदलं च गृहीत्वान्तरं कर्तव्यम् । शेषं स्पष्टार्थम् ।

अत्रोपपत्त्यर्थं भास्करभुजानयनं द्रष्टव्यम् ॥ ११-१२ ॥

वि. भा.—भुक्त्यन्तरं (रविचन्द्रयोगंत्यन्तरं) इष्टोनस्थितिदलघटिकागुणं (इष्टरहितस्थित्यर्धषष्ट्या गुणितं) षष्ट्या हृतं (षष्टिभक्तं) तदा बाहुः (भुजः) भवत्यर्थात् स्पर्शदिनन्तरं यावतीष्विष्टघटिकासु ग्रासज्ञानमपेक्षितं तावतीभिर्घटी-भी रहितेन स्थित्यर्धेन गुणितं रविचन्द्रयोगंत्यन्तरं षष्टिभक्तं तदा भुजो भवतीति, ततः फलेनानेन सूर्यचन्द्रपातान् प्रचाल्य तात्कालिकश्चन्द्रशरः साध्यः सचकोटिः, तयोः (भुजकोटयोः) वर्गयोगमूलं कर्णः स्यात् । मानैक्यार्धात् कर्णं विशोध्य शेषस्तात्कालिको ग्रासः (इष्टग्रासो) भवतीति ॥ ११-१२ ॥

अत्रोपपत्तिः

स्पर्शानन्तरं यावतीभिर्घटिकाभिर्ग्रास-ज्ञानमपेक्षितं तावतीभिर्घटीभी रहितं स्थित्यर्धं कार्यं शेषेणाऽनुपातो यदि षष्टिघटीभी रविचन्द्रयोगंत्यन्तरकला लभ्यन्ते तदेष्टोन-स्थित्यर्धघटीभिः किमित्यनुपातेन यत्फलं स भुजो भवति, अनुपातागत फलेन सूर्यचन्द्र-पातान् प्रचाल्य तात्कालिकश्चन्द्रशरः साध्यः सा कोटिः, तयोर्वर्गयोगमूलं कर्णः स्यात् ।

मानैक्यार्धात् कर्णस्य संशोधनेष्टग्रासो भवेत् । चं = चन्द्रकेन्द्रम् । सू = भूभाकेन्द्रम् । अचं = भूभाकेन्द्र केन्द्रयोरन्तरम् = कर्णः । चरं = चन्द्रकेन्द्रोपरिगत कदम्ब प्रोतवृत्ते

चन्द्रशरः=कोटिः । भर=भुजः, एतच्चापीयजात्यत्रिभुजं सरलाकारकं स्वीकृत-
माचार्येण, तदा $\sqrt{\text{कोटि}^2 + \text{भुज}^2}$ = कर्ण, पश=इष्टग्रासः । भूप+चंग=भूभा-
व्या^३+चंव्या^३=मानैक्यार्ध=भूप+पचं+पश=भूचं+इष्टग्रास=कर्ण+इष्ट-
ग्रास=मानैक्यार्ध, ∴ मानैक्यार्ध—कर्ण=इष्टग्रासः ।

सिद्धान्त शेखरे “इष्टन्यूनस्थितिदलगुणा भुक्तिविश्लेषलिप्ता पष्ठ्याभक्ता
भवति हि भुजः कोटिरिष्टेन्दुवाणः । तद्वर्गैक्योद्भवमपि पदं कर्ण एतेन हीनं
मानैक्यार्धं स्फुटमिह भवेद्वाञ्छितं छन्नमानम्” ज्ञेन श्रोपतिना, सिद्धान्त शिरोमणि
“कोटिश्च तत्काल शरोऽथकोटीदोर्वर्गयोगस्य पदं श्रुतिः स्यात् । मानैक्यखण्डं
श्रुतिवर्जितं सद्ग्रासप्रमाणं भवतोष्टकाले” श्लोकेनानेन भास्कराचार्येणाप्याचार्यो-
क्तमेवोक्तमिति ॥ ११-१२ ॥

अब इष्टग्रासानयन को कहते हैं ।

हि. भा.—रवि और चन्द्र के गत्यन्तर को इष्ट रहित स्थित्यर्ध घटी से गुणा कर
साठ से भाग देने से भुज होता है, इस फल करके सूर्य, चन्द्र और पात को चालन देकर
तात्कालिक चन्द्रशर साधन करना वह कोटि है उन दोनों (भुज और कोटि) का वर्गयोग मूल
कर्ण होता है, मानैक्यार्ध (छाद्य और छादक बिम्ब के व्यासार्ध योग) में से कर्ण को घटाने
से जो शेष रहता है वह इष्टग्रास होता है इति ॥ ११-१२ ॥

उपपत्ति ।

स्पर्श के बाद जितनी इष्ट घटी में ग्रास-ज्ञान अपेक्षित हो उस इष्ट घटी को
स्थित्यर्ध में से घटा देना, शेष से अनुपात करते हैं, यदि साठ घटी में रवि और चन्द्र की गत्य-
न्तर कला पाते हैं तो इष्टोन स्थित्यर्ध घटी में क्या इससे जो फल होता है वह भुज है,
अनुपातागत फल से चालित रवि, चन्द्र और पात से तात्कालिक चन्द्रशर साधन करना वह
कोटि है इन दोनों (भुज और कोटि) का वर्गयोग मूल कर्ण होता है, मानैक्यार्ध में से कर्ण को
घटाने से इष्ट ग्रास होता है, जैसे संस्कृतोपपत्ति में लिखित (क) क्षेत्र को देखिये, चं=चन्द्र-
केन्द्र, भू=भूभाकेन्द्र, भूचं=भूभा और चन्द्र के केन्द्रान्तर=कर्ण चंर=चन्द्रकेन्द्रोपरिगत
कदम्बप्रोतवृत्त में चन्द्रशर=कोटि, भूर=भुज, भूरचं चापीय जात्य त्रिभुज को सरल-
जात्य त्रिभुज स्वीकार कर $\sqrt{\text{भुज}^2 + \text{कोटि}^2}$ = कर्ण, पश=इष्टग्रास, भूप+चंग=भूभाव्या^३
+चंव्या^३=मानैक्यार्ध=भूप+पचं+पश=भूचं+इष्टग्रास=कर्ण+इष्टा । अतः मानै-
क्यार्ध—कर्ण=इष्टग्रास, इससे आचार्योक्त उपपन्न हुआ ।

सिद्धान्त शेखर में “इष्ट न्यून स्थिति दलगुणा भुक्तिविश्लेषभक्ताः” इत्यादि से
श्रीपति तथा “कोटिश्च तत्कालशरोऽथ कोटी” इत्यादि से सिद्धान्त-शिरोमणि में भास्करा-
चार्य ने भी आचार्योक्त के अनुसार ही कहा है, परन्तु यह आनयन ठीक नहीं है उपपत्ति
देखने ही से स्पष्ट है इति ॥ ११-१२ ॥

इदानीमिष्टग्रासात्कालानयनमाह -

असकृद्ग्रासकलोनप्रमाणयुतिदलकृतेर्विशोध्य कृतिम् ।

क्तानुरूपमेवेतिज्ञेयं विज्ञैरिति ॥ १३-१४ ॥

अब इष्ट ग्रास से कालसाधन को कहते हैं ।

हि. भा.—ग्रास रहित मानैक्यार्ध वर्ग में से तात्कालिक चन्द्रशरवर्ग को घटा कर
शेष का मूल लेकर उससे तिथिवत् असकृत्कर्म करना चाहिये अर्थात् शेष मूल को साठ से
गुणा कर रवि और चन्द्र के गत्यन्तर से भाग देने से जो फल काल हो उनसे रवि, चन्द्र और
पात को चला कर तात्कालिक चन्द्रशर साधन कर उससे फिर 'ग्रासकलो-
प्रमाणयुतिदल-कृतेः' इत्यादि से असकृत् करने से जो काल स्थिरीभूत हो उसको स्पर्शिक स्थित्यर्ध में से घटाने
से स्पर्श के बाद काल होता है अर्थात् स्पर्श के अनन्तर इतने काल में इतने इष्टग्रास होते
हैं । इसीतरह मोक्ष सम्बन्धी काल को मोक्षस्थित्यर्ध में से घटाने से शेष मोक्ष से पूर्व इष्टकाल
होता है अर्थात् मोक्ष से पहले इतने काल में इतने इष्ट ग्रास होते हैं इस तरह इष्ट ग्रास से दो
तरह का इष्टकाल होता है, एक स्पर्श काल के अनन्तर और दूसरा मोक्ष से पूर्व इति ॥ १३-
१४ ॥

उपपत्ति १

स्पर्शादि कालिक शर विदित न रहने के कारण मध्यग्रहण कालिक शर ही से
इष्ट कालानयन किया गया है जो कि ठीक नहीं है, इसलिये असकृत्प्रकार से स्फुट इष्ट काला-
नयन करवा उचित ही है, पहले इष्ट ग्रासानयन में मानैक्यार्ध — इष्टग्रास = कर्ण इसके वर्ग

में से तात्कालिक चन्द्रशर वर्ग को घटा कर जो शेष रहता है उसके मूल को साठ से गुणा कर रवि और चन्द्र के गत्यन्तर से भाग देने से जो लब्ध हो उसको स्पाशिक स्थित्यर्ध में से वा मौक्षिक स्थित्यर्ध में से घटा देना तब गृहीत इष्ट ग्रास सम्बन्धी काल होता है, इसतरह असकृन् (बार बार) कर्ण वर्ग में से तात्कालिक चन्द्रशर वर्ग को घटाकर शेष के मूल को साठ से गुणा कर रवि और चन्द्र के गत्यन्तर से भाग देने से जो फल काल हो उससे रवि, चन्द्र और पान को चला कर तात्कालिक चन्द्रशर साधन करना पुनः उससे “ग्रासकलोत्प्रमाणयुतिदल-कृतेः” इत्यादि से बार बार जो काल स्थिर हो उसको स्पाशिक स्थित्यर्ध में से घटा देना तब स्पर्श के बाद गत काल होता है, उसी काल को मौक्षिक स्थित्यर्ध में से घटाने से शेष मोक्ष से पूर्व इष्टकाल होता है, सूर्य सिद्धान्त में भी इसी तरह इष्ट ग्रास से कालानयन है, सिद्धान्त-विरोम्णि में “ग्रासोनमानैक्य दलस्य वर्गाद्विसेप कृत्या” इत्यादि संस्कृतोपपत्ति में लिखित पद्यों से भास्कराचार्य ने भी आचार्योक्तानुरूप ही कहा है इति ॥ १३-१४ ॥

इदानीं स्पर्शादिव्यवस्थामाह

अथ आक्षवलनानयन को कहते हैं

हि. भा.—पूर्वकपाल में और पश्चिम कपाल में जो सममण्डलीय नतांश है उसकी
ज्या और अक्षज्या के घात में त्रिज्या से भाग देने से जो लब्ध होता है उसका चापांश
करके ग्रह से तीन राशि पर पूर्वतः और पश्चिमतः क्रम से उत्तर और दक्षिण में ग्रह
वृत्तीय सममण्डल से नाड़ीवृत्त की पूर्वा दिशा होती है, यहाँ अग्रिम श्लोक के, 'सममण्डलात्'
इस के साथ सम्बन्ध है ॥१६॥

उपपत्ति

आन्तिवृत्त में जहाँ ग्रहस्थान है उसके ऊपर ध्रुवप्रोतवृत्त और समप्रोतवृत्त कर
दिया, ग्रह (ग्रहस्थान) से नवत्यंश व्यासार्ध से ग्रहक्षितिजसंज्ञक वृत्त कर दिया, ध्रुवप्रोत
वृत्त और समप्रोतवृत्त के अन्तर्गत ग्रहक्षितिज वृत्तीय चाप वा नाड़ीवृत्त और पूर्वापरवृत्त
के अन्तर्गत ग्रहक्षितिजवृत्तीय चाप वा ग्रहलग्नकोण (ध्रुवप्रोतवृत्त और समप्रोतवृत्त से
उत्पन्न कोण) आक्षवलन है, खस्वस्तिक में ग्रह के रहने से सममण्डलीय नतांश (ग्रहोपरि-
गत समप्रोतवृत्त और पूर्वापरवृत्त के सम्पात से खस्वस्तिक पर्यन्त) का अभाव होता है,
नाड़ीवृत्त और पूर्वापरवृत्त के सम्पात (पूर्वस्वस्तिक) में ग्रह के रहने से सममण्डलीय
नतांश नवत्यंश के बराबर होता है और नतकाल दिनाघर्ष के बराबर होता है, इन दोनों
के मध्य में ग्रह के रहने से अनुपात करते हैं यदि दिनाघर्ष तुल्य नतकाल में नवत्यंश तुल्य
सममण्डलीय नतांश पाते हैं तो इष्ट नतकाल में क्या इस अनुपात से इष्ट सममण्डलीय
नतांश प्रमाण आता है, लेकिन यह अनुपात ठीक नहीं है, ग्रह से ध्रुव पर्यन्त दूज्या
चापांश प्रथमभुज, ग्रह से समस्थानपर्यन्त उपकोटि द्वितीय भुज, अक्षांश (ध्रुव और
समस्थान के अन्तर्गत वाम्योत्तरवृत्तीय चाप) तृतीय भुज, इन तीनों भुजों से उत्पन्न
चापीय त्रिभुज में समस्थानलग्नकोण = १८०°—सममण्डलीयनतांश, ग्रहलग्नकोण =
आक्षवलन, अब अनुपात करते हैं यदि दूज्या में अक्षभुजकोणज्या = { ज्या

(१८०°—सममण्डलीय नतांश) } = सममण्डलीय नज्या, पाते हैं तो अक्षज्या में इससे ग्रह-

लग्नकोणज्या (आक्षवलनज्या आती है $\frac{\text{सममण्डलीय नज्या-अक्षज्या}}{\text{द्यु}} = \text{आक्षवलनज्या}$.)

यहाँ आचार्य ने सममण्डलीयनतांशज्या के स्थान में सममण्डलीयनतांशोत्क्रमज्या तथा द्युज्या के स्थान में त्रिज्या का ग्रहण किया है जो नितान्त अनुचित है, साधित आक्षवलनज्या का वाप करने से आक्षवलन पूर्व कपाल में उत्तर और पश्चिम कपाल में दक्षिण होता है. शिष्यधीवृद्धि में लल्लाचार्य “स्पृष्टादिकालजनतोत्क्रमशिञ्जिनीभिः” इत्यादि संस्कृतोपपत्ति में लिखित पद्यों से तथा सिद्धान्तशेखर में श्रीपति ने “नतोत्क्रमज्याऽक्षगुणाभिधातात्” इत्यादि से उत्क्रमज्या प्रकार से आक्षवलनानयन किया है जिसका खण्डन सिद्धान्तशिरोमणि में भास्कराचार्य ने “धैरुत्क्रमज्या त्रिघनैतदुक्त” इत्यादि से किया है जो त्रिबिक्कुल ठीक है, कोई कोई “खाङ्काहतं स्वद्युदलेन भक्त” इत्यादि से साधित भास्करीय आक्षवलन को ठीक कहते हैं सो अनुचित है सूर्यसिद्धान्त में भी “नतज्याऽक्षज्याक्षुण्या” इत्यादि से साधित आक्षवलन ठीक नहीं है इति ॥१६॥

इदानीमायनवलनानयनमाह

साधनं कृतमिति ॥१७॥

प्रथम आयन वलन के साधन को कहते हैं

हि. भा.—तीन राशि युक्त ग्राह्य (चन्द्रग्रहण में चन्द्र से सूर्य ग्रहण में सूर्य से) से जो
क्रान्त्यंश हो उससे उत्तर और दक्षिण नाड़ीवृत्त से तीन राशि के अन्तर पर क्रान्तिवृत्तीय
तात्कालिक पूर्वा दिशा होती है, इस क्रान्तिवृत्तीय पूर्वा दिशा से दक्षिण और उत्तर चन्द्रग्रह
होता है इति ॥१७॥

उपपत्तिः

संस्कृतोपपत्ति में लिखित (क) क्षेत्र को देखिये । प्र = प्रोत, क = कदम्ब,
ग्र = क्रान्तिवृत्त में ग्रह = चन्द्र, ग्रह के ऊपर प्रोतवृत्त और कदम्ब प्रोतवृत्त कीजिए, ग्रह
को केन्द्र मानकर नवत्यंश व्यासार्ध से ग्रहक्षितिज संज्ञक वृत्त कीजिए, इन वृत्त में प्रोत-
वृत्त और कदम्बप्रोतवृत्त के अन्तर्गत चाप वा नाड़ीवृत्त और क्रान्तिवृत्त के अन्तर्गत
चाप वा ग्रहलग्न कोण (प्रोतवृत्त और कदम्बप्रोतवृत्त से उत्पन्न) साधन वलन है । कप-
सन = ग्रहक्षितिज, स = सविमग्रह, = सविमग्रह, कप = कव = < प्रक = साधनवलन, मधु-
सन = सविमग्रह के ऊपर प्रोतवृत्त, < प्रक = ग्रहोदि = चन्द्रोदि, प्रो = बुद्ध्या-
चाप, कप्र = जिनांश, तब कप्र चापीय त्रिभुज में कोणानुपात 'यदि बुद्ध्या में ग्रहोदित्या
पाते हैं तो जिन्या में क्या' से ग्रहलग्न कोणज्या अर्थात् साधनवलनज्या =

ग्रहोदित्या. जिन्या 'इसको बुद्ध्या में परिवर्तन के बिना अनुपात करते हैं यदि जिन्या में ग्रह
वलनज्या पाते हैं तो बुद्ध्या में क्या इस से बुद्ध्यायी साधन वलनज्या पाती है,

ग्रहोदित्या. जिन्या = बुद्ध्यायी साधन वलनज्या, सविमग्रह = ६० + ४ ∴ सविमग्रहज्या =

ज्या (६० + ४) चापज्या और चापेन चापीयज्या बराबर होती है इसविज्या ज्या
(६० + ४) = ज्या (१८० - ६० - ४) = ज्या (६० - ४) = ग्रहोदित्या = सविमग्रहज्या

∴ ग्रहोदित्या. जिन्या सविमग्रहज्या. जिन्या = सविमग्रहज्या = बुद्ध्यायी साधनवलनज्या,

त्रिज्यायी आयनवलनज्या (वास्तव आयनवलनज्या) पहले लाई हुई

अक्रोज्या.त्रिज्या

सु

है, यहाँ आचार्य ने त्रिज्या और झुज्या को बराबर स्वीकार कर त्रिज्या परि-

णामन को नहीं कर के सन्निभ क्रान्तिज्या तुल्य ही आयनवलनज्या स्वीकार किया है। भास्कराचार्य से प्राचीनाचार्यों ने भी यही किया है। लल्लाचार्य ने शिष्यधीवृद्धि में 'भुजज्या और उसकी उत्क्रमज्या के एक ही स्थान में अभावत्व और परमत्व से बहुत विषयों के साधन उत्क्रमज्या ही से करते हुए वलनानयन भी उत्क्रमज्या ही से किया है। लल्लोक्तसाधन को युक्तियुक्त समझ कर श्रीपति भी उन्हीं का अनुमरण करते हैं। जैसे लल्लाचार्य कहते हैं "ग्राह्यात् सराश्रितयाद् भुजज्या" इत्यादि संस्कृतोपपत्ति में लिखित पद्य से श्रीपति भी "त्रिभवन संहितान्च ग्राह्यतो व्यस्तजीवा इत्यादि संस्कृतोपपत्ति में लिखित पद्य से लल्लोक्त के अनुसार ही कहते हैं। इन आचार्यों ने (लल्ल और श्रीपति) आयनवलन में शर संस्कार भी किया है जो युक्तिशून्यत्व के कारण ठीक नहीं है। आचार्यों के आयन वलनज्या क्रान्तिज्या ही है उसका चापांश सन्निभग्रह की दिशा उत्तर और दक्षिण आयनवलनांश होता है, भास्कराचार्य ने सिद्धान्तशिरोमणि में "युतायनांशोऽपकोटिशिञ्जनी" इत्यादि से आयनवलन का साधन ठीक किया है इति ॥१७॥

इदानीं स्पष्टवलनमाह

एकान्यदिशोर्युतिवियुतेर्ज्या प्रग्रहणमध्यमोक्षेषु ।

नज्या, अस्याध्वापं स्पष्टवलनं भवेदिति ॥१८॥

ग्रह स्पष्टवलनानयन को कहते हैं

हि. भा. — एक दिशा का आक्षवलन और आयनवलन का योग करने से तथा भिन्न
दिशा का, उन दोनों का अन्तर करने से जो होता है उसकी ज्या स्पर्शकाल, मध्यग्रहण और
मोक्षकाल में स्फुटवलनज्या होती है, इसी तरह निमीलनकाल - उन्मीलनकाल और इष्टकाल
में स्फुटवलन साधन करना । इस वलन से ग्रन्थदिशा का ग्रानयन करना अर्थात् एक वृत्त से
जितने भंश में ग्रन्थवृत्त की पूर्वा दिशा चलती है उतने भंश में ग्रन्थ दिशा चलती है
इति ॥१८॥

उपपत्ति

ग्रह के ऊपर समप्रोतवृत्त-कदम्बप्रोतवृत्त और ध्रुवप्रोतवृत्त कीजिये, ग्रह को केन्द्रमानकर
मवदयंश से ग्रह क्षितिज कीजिए, इसमें समप्रोतवृत्त और कदम्बप्रोतवृत्त के अन्तर्गत चाप
स्पष्टवलन है, ग्रहोपरिगतसमप्रोतवृत्त और ध्रुवप्रोतवृत्त से उत्पन्न ग्रहलग्नकोण आक्षवलन है
तथा ध्रुवप्रोतवृत्त और कदम्बप्रोतवृत्त से उत्पन्न ग्रहलग्नकोण आयनवलन है, दोनों का
योगान्तर करने से समप्रोतवृत्त और कदम्बप्रोतवृत्त से उत्पन्न ग्रहलग्न कोण स्पष्टवलन
होता है, सिद्धान्तसंक्षेप में “पलवलनमनेन स्पष्टयेकीकृतं” इत्यादि से श्रीपति ने, “अपक्रम-
क्षेपपलोदुसवानाम्” इत्यादि से ललाचार्य ने, तथा “तयोः पलोत्थायनयोः समाशयोः” इत्यादि
से सिद्धान्तशिरोमणि में भास्कराचार्य ने भी आचार्योक्तानुरूप ही स्पष्टवलन कहा है, केवल
लल्ल और श्रीपति ने आयनवलन और आक्षवलन के योगान्तररूप स्पष्टवलन में अर संस्कार
भी किया है जो कि अनुचित है, भास्कराचार्य ने साधित स्पष्टवलन का मानैकपार्श्ववृत्त में
परिणामन किया है, आचार्य ने त्रिज्यावृत्त में साधित स्पष्टवलन को ज्या का त्यों रक्खा है,
परिमेख के सिधे स्पष्टवलन की वस्तुतः होती है ।

एकानुपात से स्पष्टवलनानयन को दिखलाते हैं

यहाँ संस्कृतोपपत्ति में विहित (क) क्षेत्र को देखिये । अन्तिमवृत्त और पूर्वोत्तरवृत्त का

सम्पात सन्धिग्रह है = संम बिन्दु से नवत्यंश व्यासार्धवृत्त क्षान्तिवृत्त और पूर्वापरवृत्त का परमान्तरवृत्त है, स = सन्न, = क्षान्तिवृत्त और क्षितिजवृत्त का सम्पात बिन्दु । पु = पूर्वस्व-
स्तिक, पूल = सन्नाशावाप, स = मयस्थान, क = कदम्ब,

सन्न = सन्नाशाकोटिवाप, नम = क्षान्तिवृत्त और पूर्वापरवृत्त का परमान्तर = वृत्त,
संल = सन्धिग्रहमरुनान्तर < सन्न = विविन्नसन्न का उन्नतांश, तब सन्न बायींमात्र
त्रिभुज में अनुपात से

सन्नाशाकोटिज्या-विविन्नशङ्कु
त्रि = परमान्तरकोटिज्या, इसके वाप को नवत्यंश में बढ़ाने

से परमान्तर = नम होता है, तब संनम, संसपू दोनों बायीं मात्र त्रिभुजों के व्याखेप
समातीय हैं इसलिये अनुपात से

त्रि × सन्नाशा
परमान्तरज्या = सन्धिग्रह और सन्न की घन्तरज्या, इसके वाप को सन्न में बढ़ाने से

सन्धिग्रह होता है, ग्र = ग्रह, संग्र = सन्धिग्रह और ग्रह का घन्तर ग्रह विदित है, नन =
सन्धिग्रह और ग्रह की घन्तरकोटि = < सक्र संग्र = उपकोटिवाप, तब सक्र बायीं
त्रिभुज में अनुपात करते हैं

सन्धिग्रहग्रहान्तरकोटिज्या × परमान्तरज्या
उपकोटिज्यासाध = ज्या < ग्र = स्पष्टवसनज्या, इसका वाप

करने से स्पष्ट वसन होता है ॥१८॥

इदानीं ग्रहो चन्द्रग्रहमाह

आद्यन्तयोः सङ्ग्राहः कुम्भः सङ्ग्रहोऽर्धतोऽप्यधिके ।

आते स कुम्भताम्रः सर्वग्रहो कपिलवर्तः ॥१९॥

सु. भा.—आद्यन्तयोश्चन्द्रः स ग्राहो वर्त्तो भवति । अर्धग्रहलादी
ग्रहान्ते च चन्द्रो ग्राहवर्त्तो भवति । कुम्भताम्रः कुम्भरक्तो विद्याभ्यनन्द-
विरत्नवर्त्तः । केचं स्पष्टार्थः । स्वस्पष्टान्ते ग्राहवर्त्तः कुम्भोर्धोरेखादिवास्तरोक्त-
येतदनु रूपमेव ॥१९॥

वि. भा.—आद्यन्तयोः (ग्रहलादी ग्रहान्ते च) चन्द्रः सङ्ग्राहो (ग्राहवर्त्त-
सहितः) भवति । सङ्ग्रहो चन्द्रः कुम्भवर्त्तो भवति, अर्धतोऽप्यधिके आते
(अर्धार्धिके ग्रहो) कुम्भताम्रः (कुम्भरक्तो विद्याभ्यनन्दविरिति) सर्वग्रहो
चन्द्रः कपिलवर्त्तो भवतीति ॥१९॥

अत्रोपपत्तिः

वर्णसंयोगेन वर्णान्तरमुत्पद्यते, भूभाकृष्णा, चन्द्रबिम्बं पीतमतस्तयोः संयोगे न्यूनाधिक्यस्थितिवशेन भिन्नं भिन्नं वर्णान्तरं दृग्गोचरीभूतं भवति । सूर्यग्रहणे हि छाद्यच्छादकयोः (सूर्याचन्द्रमसोः) संयोगाभावात् वर्णान्तरं नैव जायते, सूर्यसिद्धान्ते, शिष्यधीवृद्धिदे, सिद्धान्तशिरोमणौ चैवमेव रविचन्द्रयोर्ग्रहणे वर्ण उक्तोस्ति सिद्धान्तशेखरेऽपि “आदावन्ते वहलविलसद्भूमधूम्रो विधुः स्यादर्धच्छन्नः कलयति पुनः कालतां कज्जलस्य । अर्धादूर्ध्वं कवलिततनुः कृष्णताम्रः पिशङ्गः सर्वप्रासे भवति सविता सर्वदा कृष्ण एव” श्रीपतिनाजनेनैवमेवोच्यत इति ॥ १६ ॥

अब ग्रहण में चन्द्रवर्ण को कहते हैं

हि. भा.—ग्रहण के आदि में और अन्त में चन्द्र का घुम (बूझा) वर्ण होता है क्षण्ड ग्रहण में कृष्ण वर्ण होता है । अर्वाधिक ग्रहण में कृष्णताम्र (कालापनयुक्त लाल) वर्ण होता है, सर्वग्रहण में चन्द्र का कपिल वर्ण होता है इति ॥ १६ ॥

उपपत्ति

वर्ण के संयोग से वर्णान्तर बनता है, भूभाकृष्णवर्ण है और चन्द्रबिम्ब पीत (पीला) वर्ण है इस लिये दोनों का संयोग होने से न्यूनाधिक्य स्थितिवश से भिन्न-भिन्न वर्णान्तर देखने में आता है, सूर्यग्रहण में छाद्य और छादक (सूर्य और चन्द्र) के संयोगाभाव से वर्णान्तर उत्पन्न नहीं होता है, सूर्यसिद्धान्त, शिष्यधीवृद्धिद, सिद्धान्तशिरोमणि, सिद्धान्तशेखर में इसी तरह ग्रहण में वर्ण कहा है इति ॥ १६ ॥

इदानीमस्याध्यायस्योपसंहारमाह

इति श्रीब्रह्मगुप्तविरचिते ब्राह्मस्फुटसिद्धान्ते

चन्द्रग्रहणाधिकारश्चतुर्थः समाप्तः

अब इस अध्याय के उपसंहार को कहते हैं

हि. ५१.—मान (छाद्य बिम्ब और छादक बिम्ब के मान) विमर्दावर्ग, स्थित्यवर्ग, वलन (आक्षवलन, आयनवलन और स्पष्टवलन) इष्टग्रास, मध्यग्रहण समय, एतदादि विषयों में बीस आर्यांश्लोक हैं जिसमें ऐसा चौथा चन्द्रग्रहणाध्याय है इति ॥२०॥

इति श्रीब्रह्मगुप्तविरचित ब्राह्मस्फुटसिद्धान्त में चन्द्रग्रहणाधिकार (चतुर्थाधिकार) समाप्त हुआ ॥

ब्राह्मस्फुटसिद्धान्तः ७

सूर्यग्रहणाधिकारः

ब्राह्मस्फुटसिद्धान्तः

सूर्यग्रहणाधिकारः

अथ सूर्यग्रहणाधिकारो व्याख्यायते तत्रोदा तदारम्भप्रयोजनमाह

दृग्गणितैक्यं न भवति यस्मात् पञ्चज्याया रविग्रहणे ।

तस्माद्यथा तदैक्यं तथा प्रवक्ष्यामि तिथ्यन्ते ॥१॥

सु. भा.—उदयज्या अग्रा । मध्यज्या=खलमनतांशज्या । रविशङ्कुः । दृग्गतिः=वित्रिमशङ्कुः । दृक्षेपः=वित्रिमनतांशज्या । एवमार्यभटादिभिः पञ्चज्याया रविग्रहणे यदानयनमुपनिबद्धं तद्यस्माद् दृग्गणितैक्यं न भवति तस्माद्यथा तयोर्दृग्गणितयोरैक्यं स्यात् तथाऽऽनयनमहं प्रवक्ष्यामीति । तिथ्यन्ते इत्यस्याग्रे सम्बन्धः । सम्प्रति प्रसिद्धसूत्रसिद्धान्तेऽपि पूर्वोक्तपञ्चज्ययैवाकर्णग्रहणा-
नयनम् । पोलिशे च चन्द्रस्यापि पृथक् सूर्यग्रहणे पञ्चज्याः साधिता इति दशज्या-
विधानेन तत्र रविग्रहणमुपनिबद्धम् । तथा च स्वटीकायां चतुर्बोधाचार्यः—

‘पञ्चज्याया पञ्चज्याविधानेन रविग्रहणं यदाचार्यैरुपनिबद्धम् । तद्यथा । उदयज्या, मध्यज्या, शङ्कुज्या, दृग्गतिज्या, दृक्षेपज्या च । ताभिरार्यभटादि-
भिस्तथा पोलिशतन्त्रे पञ्चज्याश्चन्द्रमसः स्वदिनगतशेषचरदलकान्त्यादिभिः
कल्पिताः । एवं तत्र दशज्याविधानेन रविग्रहणं यदुपनिबद्धं तादृशममान्ते भवति ।
ये च तत्र दोषास्तानाचार्य एव वक्ष्यति तन्त्रपरीक्षाध्याये वयमस्मि तत्रैव व्याख्या-
स्यामः’ ।

वि. भा.—यस्मात् कारणात् रविग्रहणे (सूर्यग्रहणे) पञ्चज्याया (उदयज्या,
मध्यज्या, रविशङ्कुः, वित्रिमशङ्कुः, दृक्षेपः) ऽऽर्कभटादिभिर्यदानयनमुपनिबद्धं
ततो दृग्गणितैक्यं (द्वाम्नां दृग्गणिताभ्यां समत्वं) न भवति, तस्मात् कारणात्
यथा तदैक्यं (तयोर्दृग्गणितयोः समत्वं) भवेत्तथाऽऽनयनमहं प्रवक्ष्यामि, तिथ्यन्ते
इत्यस्याग्रे सम्बन्धः । उदयज्या=अग्रा, मध्यज्या=दक्षमलमनतांशज्या, वित्रिम-
शङ्कुः=दृग्गतिः, दृक्षेपः=वित्रिमनतांशज्या सूर्यसिद्धान्तेऽपि पूर्वोक्तपञ्चज्य-
यैव सूर्यग्रहणासाधनम् । पोलिशसिद्धान्ते तु सूर्यग्रहणे चन्द्रस्यापि पृथक् पञ्चज्याः
साधिताः सन्ति तेन तत्र दशज्याविधानेन सूर्यग्रहणमुपनिबद्धमिति ॥१॥

प्रथम सूर्यग्रहणाधिकार प्रारम्भ किया जाता है, पहले उसके आरम्भ करने का प्रयोजन कहते हैं

हि. भा.—जिस कारण से सूर्यग्रहण में पञ्चज्या (उदयज्या, मध्यज्या, रविशङ्कु, वित्रिभशङ्कु, दृक्षेप) से ग्रायंमटादि आचार्यों ने जो भ्रानयन किया है उससे ह्यग्नितैक्य (विषोपलब्ध और गणितागत विषयों की तुल्यता) नहीं होता है उस कारण से जैसे उनका ऐक्य (विषोपलब्ध और गणितागत विषयों के समत्व) हो वैसे मैं भ्रानयन को कहता हूँ, तिथ्यन्ते इसका भाग्य से सम्बन्ध है, उदयज्या = अग्रा, मध्यज्या = दशमलग्ननतांशज्या वित्रिभशङ्कु = ह्यगति, दृक्षेप = वित्रिभनतांशज्या, सूर्यसिद्धान्त में भी पूर्वोक्त पञ्चज्या ही से सूर्य-ग्रहण का भ्रानयन है, पौलिशसिद्धान्त में सूर्यग्रहण में चन्द्र की पृथक् पञ्चज्या साधित है इसलिए वहाँ दशज्या विधान से सूर्यग्रहण उपनिबद्ध है इति ॥१॥

इदानीं लम्बननत्योर्भावाभावस्थानमाह

वित्रिभलग्नसमेऽर्के न लम्बनं तदधिकोनके भवति ।

तस्य क्रान्तिज्योदक् यदाऽक्षजोवा समा न तदा ॥२॥

कोउज्या < त्रि $\therefore \frac{\text{त्रि}}{\text{परमलंकोउज्या}} > १$ वा $\frac{\text{पृहज्या}}{\text{हज्या}} = \frac{०}{०} > १$ इति गणित-
वैचित्र्यं बुधैर्विभावनीयमिति ॥२-३॥

अब लम्बन और नति के आवाभावस्थान को कहते हैं

हि. भा.—तिथ्यन्त (गणितगत अमान्त काल) में त्रिप्रश्न में कथित विधि से
लम्बन साधन करना उसमें तीन राशि घटाने से वित्रिभलग्न होता है, वित्रिभलग्न के तुल्य
रवि के रहने से लम्बन नहीं होता है अर्थात् लम्बनाभाव होता है, वित्रिभ से रवि के
अधिक और अल्प रहने से लम्बन होता है, तथा जब वित्रिभ की उत्तर क्रान्तिज्या स्वदेशीय
अक्षज्या के बराबर होती है तब नति का अभाव होता है, इससे अन्यथा नति होती है,
लम्बन और नति के सम्भव रहने पर देशीय रात्र्युदयमानों से “ऊनस्य भोग्योऽधिकमु-
क्तमुक्ते यन्मोदयाद्भ्यः” वह त्रिप्रश्नोक्तविधि कर के वित्रिभ की सतघटी साधन करना

तदनन्तर विविध की चरासु से 'दिनगतशेषात्पस्य' इत्यादि विधि से विविधशङ्कु का साधन करना चाहिये ॥२-३॥

उपपत्ति

लग्नोत्पन्न नवत्यंशवृत्त (दृक्षेपवृत्त) क्रान्तिवृत्त में जहां लगता है वही विविधलग्न है, विविधलग्न के बराबर रवि के रहने से स्पष्टलम्बनाभाव होता है, रवि के ऊपर और लम्बित रवि के ऊपर कदम्बप्रोतवृत्तद्वय क्रान्तिवृत्त में जहां-जहां लगता है तदनन्तगत क्रान्तिवृत्तीय चाप (रवि से लम्बित रविस्थान पर्यन्त) रवि का स्पष्ट लम्बन है, परन्तु विविधस्थान में रवि के रहने से उसके ऊपर दृग्वृत्त तथा रवि के ऊपर और लम्बित रवि के ऊपर कदम्ब प्रोतवृत्त एक ही दृक्षेपवृत्त होता है इसलिये वहां स्पष्ट लम्बनाभाव होता है, अतः "विविधलग्नसमेर्द्धेन लम्बनम्" यह आचार्योक्त युक्ति-युक्त है इति ॥

गर्भीयामान्तकाल में स्थानाभिप्रायिक रवि और चन्द्र एक ही बिन्दु में होते हैं, इसलिए एक ही दृग्वृत्त में लम्बितरवि और लम्बित चन्द्र होते हैं, लम्बित रवि से लम्बितचन्द्र पृष्ठ में लम्बित होते हैं इसलिए विविध से रवि के अल्प रहने पर लम्बित रव्युपरिगत कदम्बप्रोतवृत्त क्रान्तिवृत्त में जहां लगता है उससे अधोभाग में लम्बितचन्द्रपरिगत कदम्बप्रोत-वृत्त क्रान्तिवृत्त में लगेगा इसलिए यहां शीघ्रगतिग्रह (लम्बितचन्द्रस्थान) से मन्दगतिग्रह (लम्बितरविस्थान) के आगे रहने के कारण युति गम्य होती है अतः गर्भीयामान्त से पृष्ठीया-मान्त स्पष्टलम्बनान्तर कर के पश्चात् होता है इसलिये गर्भीयामान्तकाल में स्पष्टलम्बना-न्तर जोड़ने से पृष्ठीयामान्तकाल होता है, विविध से रवि के अधिक रहने पर लम्बित रवि से लम्बितचन्द्र अधोभाग में होते हैं, इसलिये लम्बित रव्युपरिगत कदम्बप्रोतवृत्त और क्रान्तिवृत्त के सम्पात से लम्बितचन्द्रोपरिगतकदम्बप्रोतवृत्त और क्रान्तिवृत्त का सम्पात ऊपर होता है अतः मन्दगतिग्रह (लम्बित रविस्थान) से शाघ्रगतिग्रह (लम्बित-चन्द्र स्थान) के आगे रहने के कारण युति गत होती है, इसलिये गर्भीयामान्त काल में स्पष्टलम्बनान्तर को श्रद्धा करने से पृष्ठीयामान्तकाल होता है अतः 'तदधिकोनके भवति' यह आचार्योक्त युक्ति-युक्त है, यहां संस्कृतोपपत्तिस्थ (क) क्षेत्र को देखिये ॥२-३॥

अब नति के सम्बन्ध में विचार करते हैं

यहां संस्कृतोपपत्तिस्थ (ख) क्षेत्र को देखिये, ख=खस्वस्तिक, वि=विविध, र= क्रान्तिवृत्त में रवि, लंर=लम्बित रवि, लंरस्था=लम्बित रविस्थान, रवि से लम्बित रवि-स्थान पर्यन्त दृग्लम्बन है, लम्बित रवि से लम्बितरविस्थान पर्यन्त रवि की नति है, रवि से लम्बित रविस्थान पर्यन्त रवि का स्पष्टलम्बन है, खर=रविनतांश, खवि=दृक्षेप-चाप, खविर, तथा दृग्लम्बन—नति, स्पष्टलम्बनोत्पन्न चापीमज्जात् त्रिभुज का व्याख्येय सजातीय है इसलिये अनुपात करते हैं यदि दृग्लम्बना में दृक्षेत्र पाते हैं तो दृग्लम्बनान्तरा में

कहा इससे रवि की नतिज्या आती है, नति का मानयन दृक्क्षेप के अधीन है इसीलिये दृक्-क्षेप का अभाव रहने से नति का भी अभाव होना निश्चित है, आचार्य स्वल्पाक्ष देश में स्वल्पाक्षर से याम्योत्तरवृत्त ही में विनिम की स्थिति मानकर दिनार्धकाल की तरह क्रान्ति और अक्षांश के संस्कार से उत्तर क्रान्तिरूप अक्षांश में नतांशाभाव स्थान लाये हैं इसलिए 'तस्य क्रान्तिज्योदक् यदाऽक्षजीवा स्या न तदा' यह आचार्योक्त युक्तियुक्त है। सूर्यसिद्धान्त-शिरोमणि में भास्कराचार्य ने "न सम्बन्धं विनिमलम्भतुल्ये" इत्यादि से आचार्योक्त के अनुरूप ही कहा है ॥

अब प्रसङ्ग से दृक्क्षम्बन का परमत्व कहाँ होता है इसके लिये विचार करते हैं

भूकेन्द्र से और भूपृष्ठ से स्वकक्षास्थ रविकेन्द्रगत रेखाद्वय चन्द्रकक्षा में जहाँ-जहाँ लगता है तदन्तर्गत चन्द्रगोलीय दृग्बृत्तचाप रविलम्बन है, इसी तरह भूकेन्द्र से और भूपृष्ठ से चन्द्रकक्षास्थ चन्द्रकेन्द्रगत रेखाद्वय रविकक्षा में जहाँ-जहाँ लगता है तदन्तर्गत रविगोलीय दृग्बृत्तचाप चन्द्रलम्बन है, इस तरह एक त्रिभुज बनता है, भूकेन्द्र से ग्रहकेन्द्र (रविकेन्द्र या चन्द्रकेन्द्र) पर्यन्त ग्रहकर्ण एक भुज, भूपृष्ठ से ग्रहकेन्द्र (रविकेन्द्र या चन्द्रकेन्द्र) पर्यन्त पृष्ठकर्ण द्वितीयभुज, भूव्यासार्ध तृतीयभुज इन भुजों से उत्पन्न त्रिभुज में पृष्ठकर्ण और भूव्यासार्ध से उत्पन्न कोण = 180° - पृष्ठीयनतांश, कोणज्या और कोणोन-आर्धांशज्या बराबर होती है इसलिये ज्या $(180^\circ - \text{पृष्ठीयनतांश}) = \text{पृष्ठीय दृग्ज्या}$, तब अनुपात करते हैं यदि ग्रहकर्ण में पृष्ठीय दृग्ज्या पाते हैं तो भूव्यासार्ध में क्या इससे ग्रहलग्नकोणज्या (दृक्क्षम्बनज्या) आती है, उसका स्वरूप यह है

$\frac{\text{पृष्ठज्या} \cdot \text{भूव्यासार्ध}}{\text{ग्रहकर्ण}} = \text{दृक्क्षज्या}$, इसमें ग्रहकर्ण और भूव्यासार्ध स्थिर है अतः सिद्ध हुआ कि

पृष्ठीय दृग्ज्या का परमत्व जहाँ हों, वही दृक्क्षम्बनज्या का भी परमत्व होगा, लेकिन पृष्ठीय दृग्ज्या का परमत्व पृष्ठ क्षितिज में ग्रह के रहने से होता है अतः पृष्ठ क्षितिज ही में दृक्क्षम्बन का परमत्व सिद्ध हुआ।

अब नति का परमत्व कहाँ होता है विचार करते हैं

$\frac{\text{दृक्क्षेप} \times \text{दृक्क्षज्या}}{\text{दृग्ज्या}} = \text{नति स्वल्पान्तर से, तथा सम्बन्धानुपात 'त्रिज्यातुल्य पृष्ठीय$

दृग्ज्या में यदि परमक्षम्बनज्या पड़े है तो दृष्टपृष्ठीयदृग्ज्या में क्या' से दृष्टदृक्क्षम्बनज्या

आती है, $\frac{\text{परमक्षम्बनज्या} \cdot \text{पृष्ठज्या}}{\text{दृग्ज्या}} = \text{दृक्क्षज्या}$ इससे नति के स्वरूप में उत्पन्न देने से

$\frac{\text{दृक्क्षेप} \cdot \text{परमक्षम्बनज्या} \cdot \text{पृष्ठज्या}}{\text{दृग्ज्या}^2} = \text{नति}$ यही यदि पृष्ठज्या = दृग्ज्या तब ही "कक्षयोरन्तरं यत् स्यादिति

सर्वतोऽपि तत्" यह भास्करोक्त समीचीन हो सकता है परन्तु सर्वदा पृहज्या=हज्या नहीं होती है अतः भास्करोक्त वह समीचीन नहीं है। पूर्वोक्त नतिस्वरूप में यदि दृक्क्षेप को

स्थिर माना जाय तब $\frac{\text{पृहज्या}}{\text{हज्या}}$ इसका परमत्व जहाँ होगा वहीं नति का भी परमत्व

होगा, परन्तु $\frac{\text{पृहज्या}}{\text{हज्या}}$ इसका परमत्व कहाँ होता है इसके लिये विचार करते हैं। पृष्ठीय-

नतांश=पृन, गर्भीयनतांश=न, हग्लम्बन=लं, तब पृन=न+लं, चापयोरिष्टयोरित्यादि

से ज्या (न+लं)=पृहज्या= $\frac{\text{हज्या} \cdot \text{लंकोज्या} + \text{शं} \cdot \text{लंज्या}}{\text{त्रि}}$ छेदगम से पृहज्या·त्रि=हज्या·

लंकोज्या+शं·लंज्या लेकिन $\frac{\text{पलंज्या} \cdot \text{पृहज्या}}{\text{त्रि}} = \text{लंज्या}$, उत्थापन देने से पृहज्या·त्रि=

हज्या·लंकोज्या+ $\frac{\text{शं} \cdot \text{पलंज्या} \cdot \text{पृहज्या}}{\text{त्रि}}$ अतः पृहज्या·त्रि^२=हज्या·लंकोज्या·त्रि+शं·पलंज्या·

पृहज्या समशोधन करने से पृहज्या·त्रि^२—शं·पलंज्या·पृहज्या=पृहज्या (त्रि^२—शं·पलंज्या)

=हज्या·लंकोज्या·त्रि, अतएव $\frac{\text{पृहज्या}}{\text{हज्या}} = \frac{\text{लंकोज्या} \cdot \text{त्रि}}{\text{त्रि}^2 - \text{शं} \cdot \text{पलंज्या}}$ इस स्वरूप को देखने से सिद्ध

होता है कि जहाँ शङ्कु और लम्बन कोटिज्या का परमत्व होगा वहीं $\frac{\text{पृहज्या}}{\text{हज्या}}$

इसका भी परमत्व होगा, परन्तु शङ्कु और लम्बनकोटिज्या का परमत्व विभिन्न स्थान ही में होता है अतः विभिन्न स्थान ही में नति का परमत्व सिद्ध हुआ, इससे म. म. पण्डित श्री सुधाकर द्विवेदी जी का सूत्र उपपन्न होता है "कुगर्भनभ्रांशगुणेन भक्त" इत्यादि संस्कृतोपपत्तिस्थ सूत्र को देखिये ॥

$$\text{पूर्वसिद्धस्वरूप} = \frac{\text{पृहज्या}}{\text{हज्या}} = \frac{\text{लंकोज्या} \cdot \text{त्रि}}{\text{त्रि}^2 - \text{शं} \cdot \text{पलंज्या}} \quad \text{सस्वस्तिक में रवि के रहने से}$$

$$\text{शं} = \text{त्रि}, \text{लंकोज्या} = \text{त्रि}, \text{इसलिये सस्वस्तिक में } \frac{\text{पृहज्या}}{\text{हज्या}} = \frac{\text{त्रि} \cdot \text{त्रि}}{\text{त्रि}^2 - \text{त्रि} \cdot \text{पलंज्या}}$$

$$= \frac{\text{त्रि}^2}{\text{त्रि} (\text{त्रि} - \text{पलंज्या})} = \frac{\text{त्रि}}{\text{परलम्बनकोट्युत्क्रमज्या}} \quad \text{लेकिन सस्वस्तिक में रवि के रहने से}$$

$$\text{पृहज्या} = 0 \text{ तथा हज्या} = 0, \therefore \frac{\text{पृहज्या}}{\text{हज्या}} = \frac{0}{0} = \frac{\text{त्रि}}{\text{परलम्बनकोट्यज्या}} \quad \text{लेकिन परलम्बन-}$$

कोउज्या < त्रि. $\therefore \frac{\text{त्रि}}{\text{परलम्बन कोउज्या}} > 1$ वा $\frac{\text{पृष्ठज्या}}{\text{हज्या}} = \frac{0}{0} > 1$ इस गणितविचित्रता को समझना चाहिये ॥२-३॥

(१) यत्र देशे चतुर्विंशतिरक्षांशास्तत्र यदा रविचन्द्रौ तुलादिगौ भवतस्तदोदयकाले रविरेव लग्नम् । खस्वस्तिके च तत्स्थितौ पूर्वापरवृत्तानुकारकमेव क्रान्तिवृत्तं हृवृत्तं च भवति, हृवृत्तस्य क्रान्तिवृत्ताकारत्वात्तस्मिन्नेव हृवृत्ताकारे क्रान्ति वृत्ते चन्द्रोऽवलम्बितो भवेत्, तेन तत्र चन्द्रनतिः = ०, तथा चन्द्रशरः = ०, रविनतिः = ० तेन स्पष्टोऽत्र बाणो नति-संस्कृत इत्यादिना स्पष्टशरः = ०, तत्र स्पष्टनतिरपि = ० वित्रिभलग्नोद्भवशरेण संस्कृता रविनतिश्चन्द्रहृक्षेपचापम् = रविनति ± वित्रिभलग्नोद्भवशरः = ० ± वित्रिभलग्नोद्भवशरः = वित्रिभलग्नोद्भवशर । परं मिदं चन्द्र हृक्षेपचापं निरर्थकं यतः स्पष्टनत्यर्थमेव हृक्षेपस्य प्रयोजनं भवति परमत्र स्पष्टनतिः = ०, तेन हृक्षेपतो न किमपि कार्यं चलिष्यत्यतो भास्करोक्त खण्डनं युक्तियुक्तमिति ॥

ब्राह्मगुप्तोक्त चन्द्रहृक्षेपचाप के भास्करकृत खण्डन को कहते हैं ।

जिस देश में चौबीस २४ अक्षांश है वहाँ जब रवि और चन्द्र तुलादि में होते हैं तब उदयकाल में रवि ही लग्न होते हैं, खस्वस्तिक में रहने से पूर्वापर वृत्त के सहश ही क्रान्ति-वृत्त और हृवृत्त होता है, क्रान्ति वृत्ताकार हृवृत्त के रहने से उसी हृवृत्त में चन्द्रलम्बित होते हैं इसलिये चन्द्रनति = ०, चन्द्रशर = ०, तथा रविनति = ०, अतः ‘स्पष्टोऽत्र बाणो नतिसंस्कृतः’ इत्यादि से स्पष्टशर = ०, स्पष्टनति भी = ०, वित्रिभलग्नोत्पन्नशर संस्कृत रविनति चन्द्र हृक्षेप चाप होता है, रविनति ± वित्रिभलग्नोत्पन्नशर = ० ± वित्रिभलग्नोत्पन्नशर = वित्रिभलग्नोत्पन्नशर लेकिन यह चन्द्रहृक्षेप चाप निरर्थक है क्योंकि स्पष्टनति ही के लिये हृक्षेप चाप का प्रयोजन होता है, लेकिन यहाँ स्पष्टनति = ०, इसलिये हृक्षेप से कौन सा काम चलेगा ? भास्करोक्त यह खण्डन ठीक है इति ॥

अत्र 'सौम्य याम्येषुणा रहितयुतमुदीच्या' मिति श्रीपत्युक्तिः 'एक दिशो-
योगो भिन्नदिशोरन्तरमित्युक्त्या" परिवर्त्तिता भास्करेणेति ॥ ९-१० ॥

अब रवि और चन्द्र के दृग्गति साधन को कहते हैं ।

हि. भा.—उत्तर वित्रिभनति रहने पर वित्रिभलग्न से जो उत्तर वा दक्षिण शर है उसको वित्रिभलग्न के शंकुचाप में क्रम से हीन और युत करना, दक्षिण नति में उसी शंकु-चाप को उत्तर शरचाप करके जोड़ना और दक्षिण शर चाप करके हीन करना तब जो हो उसकी ज्या चन्द्र का वित्रिभशंकु (दृग्गति) होती है, सूर्य का पूर्वसाधित वित्रिभशंकु ही वास्तव दृग्गति होता है, वित्रिभलग्न दृङ्मण्डल और क्रान्तिवृत्त के सम्पात में सूर्य की दृग्गति होती है, दृक्षेपवृत्त और विमण्डल के सम्पात में चन्द्र दृग्गति होती है अर्थात् दृक्षेपवृत्त क्रान्तिवृत्त में जहां लगता है उस बिन्दु का वित्रिभलग्नशंकु सूर्य की दृग्गति होती है, वही दृक्षेपवृत्त चन्द्रविमण्डल में जहां लगता है उस बिन्दु का शंकु चन्द्रदृग्गति है इति ॥ ९-१० ॥

उपपत्ति

दृक्षेप वृत्त क्रान्तिवृत्त में जहां लगा है वहां से विमण्डलपर्यन्त दृक्षेपवृत्त में स्वल्पा-न्तर से वित्रिभलग्नशर है । इसलिये वित्रिभ की उत्तर नति और वित्रिभ के उत्तर शर रहने से दोनों का योग करने से खस्वस्तिक से विमण्डल पर्यन्त दृक्षेपवृत्त में चन्द्रदृक्षेप चापांश = वित्रिभनतांश + वित्रिभशर, इसको नवत्यंश में से घटाने से चन्द्रदृग्गतिचापांश = ९० - वित्रिभन - वित्रिभश = वित्रिभशंचा - वित्रिभश, दक्षिण वित्रिभशर में चन्द्रदृक्षेप चापांश = वित्रिभनतांश - वित्रिभश, अतः शंकुचापांश = ९० - वित्रिभन + वित्रिभश = वित्रिभशंचा + वित्रिभशर । दक्षिण नति में विलोम संस्कार करना चाहिये । इससे चन्द्रदृग्गति साधन उपपन्न होता है । दृक्षेप वृत्त क्रान्ति वृत्त के ऊपर लम्बरूप है, विमराडल के ऊपर नहीं; इस-लिये चन्द्रदृक्षेप से जो दृग्गति होती है वह कदम्ब प्रोत वृत्त में नहीं होता है अतः उसका संस्कार करने से स्फुट नति नहीं होती है, भास्कराचार्य भी पहले इस मत के अनुसार 'दृज्यैव या वित्रिभलग्नशंकोः" इत्यादि से चन्द्रदृक्षेप साधन कर उसके वस से स्पष्टनति कर के पीछे सूर्यग्रहणाधिकारान्त में 'शशिदृक्षेपार्थं यद्वित्रिभलग्नेषुणात्र संस्करणम्" इत्यादि से इस आनयन को खण्डित कर दिया, यहां 'सौम्ययाम्येषुणा रहितयुतमुदीच्याम्' इस श्रीपत्युक्ति को भास्कराचार्य ने 'एकदिशोर्योगो भिन्नदिशोरन्तरम्' से परिवर्त्तित कर दिया है, इति ॥ ९-१० ॥

इदानीं स्पष्टां नतिमाह ।
